INTRODUCTION

The data in this report were collected as part of the NOAA program Fisheries-Oceanography Coordinated Investigations (FOCI). These data were obtained as part of an ongoing effort to describe the environment of the Shelikof Strait region of Alaska and understand how it relates to the recruitment of walleye pollock, Theragra chalcogramma. Background studies, emphasizing areal distribution and seasonal development (March-October) of zooplankton communities, were conducted in 1985 and are reported by Siefert et al. (1988). We report here on the vertical distribution and composition of zooplankton, including ichthyoplankton, from this region during early May 1986. A subsequent report will provide comparable data for late May 1987. Data summarized in these various reports are undergoing analysis and will be the subjects of more detailed manuscripts, some currently in preparation.

METHODS

Samples were collected during FOCI cruise 2MF86 aboard the NOAA Ship Miller Freeman from 1-19 May 1986 (Incze et al. 1987). Figure 1 shows the area studied during the cruise and Figure 2 shows the locations of stations sampled for vertical distributions of zooplankton.

Part of the sampling focussed on three geographical areas:

Shelikof Strait (station 166); the sea valley between Chirikof Island and the Semidi Islands (122, 125); and the shallow region between the Semidi Islands and Sutwik Island (147, 157). The paired stations (numbers in parentheses above) represent sampling during daylight and darkness; while the single collection in Shelikof Strait was due to gear malfunction which could not be corrected in time to sample under both conditions. Additional sampling (stations 78-95) was conducted about a radar-tracked drifter drogued at 35 m and deployed in an area of high larval pollock abundance. The drifter was followed by the ship to allow us to examine diel movements of these larvae and other zooplankton. This drifter study continued for four days with some sampling, but operations slated to collect vertically distributed plankton samples had to be curtailed after the second day due to sea state. Later in the cruise, additional diel data were collected at stations 119-121.

Vertically distributed plankton samples were obtained from discrete depths with a MOCNESS sampler (Wiebe et. al. 1976) equipped with 153 um mesh nets. A mechanical flowmeter was used to estimate the volume of water filtered by the nets; and depth, temperature and floourescence were continuously recorded. Nets were opened and closed to sample the following nominal depth intervals, as allowed by station depth: 0-15, 15-30, 30-45, 45-60, 60-80, 80-100, 100-150 and 150-200 m. Samples were preserved in 5% buffered formalin:seawater for later laboratory analysis.

In the laboratory, invertebrates were sorted into taxonomic categories emphasizing the most abundant species, as well as those taxa of particular interest to recruitment studies of walleye pollock larvae. A list of these categories is given in Table 1, with definitions of abbreviations used throughout this report. Ichthyoplankton were identified to the lowest taxonomic level possible. A summary of ichthyoplankton taxa found during this study is listed in Table 2.

Samples were sorted at the Polish Sorting Center in Szczecin, Poland and identifications made in Poland were verified by biologists at the Northwest and Alaska Fisheries Center in Seattle. Ichthyoplankton were removed and identified from the entire sample prior to sorting invertebrate zooplankton. After ichthyoplankton were removed from the sample the sorting procedures described below were followed. Large organisms such as shrimp and jellyfish were removed and noted. The sample was then split with a Folsom plankton splitter to obtain a subsample with approximately 100-200 organisms $\geq 5\text{mm}$ in their maximum dimension, however splits were not made beyond 1/64 of the original sample. With a few exceptions (decapod larvae, euphausiid furciliae and larvaceans), these "large organisms" were removed from the sample, identified and tabulated. Next, one or two smaller subsamples were examined for all remaining taxa. The first small subsample was taken so as to obtain approximately 300-500 organisms. This subsample often provided sufficient counts (at least 30) of most of the taxa of particular

interest to the recruitment study. If it did not, then a second subsample was sorted for these organisms.

RESULTS

Invertebrate and ichthyoplankton taxa found in each sample are listed by station in Appendices 1 and 2, respectively. Taxa are listed in order of abundance and each list includes: the number of organisms counted; the fraction of the sample from which they were counted (sub/fac); their concentration per $10m^3$ (invertebrate zooplankton) and $1000m^3$ (ichthyoplankton); and the percent of either the invertebrates or the ichthyoplankton that each taxon represents in the sample. In each appendix, samples are identified by station numbers, location is given to tenths of a degree of latitude and longitude, date and time are GMT, station depth and sample intervals are in meters, volume filtered is expressed in cubic meters and net mesh is in micrometers.

With some invertebrate categories, we typically did not spend the time to identify and record all species encountered. However, notes were kept on the most abundant species found. These species are listed in Table 3.

DISCUSSION

Care must be taken when using these data for quantitative comparisons. Not all taxa were quantitatively retained with a

net of 153 um mesh. The width of the widest opening in the net (the diagonal measure) is approximately 216 um, therefore organisms with a minimum dimension less than this would not be retained consistently. Some of the obvious taxa not quantitatively retained because of size are: many invertebrate eggs and larvae; some copepod nauplii; early copepidite stages of Pseudocalanus spp. (C2 and C1) and Acartia spp.; Metriiididae C1; all stages of Oithona spp. most common in the Gulf of Alaska; and other small copepods. Taxa (size/life history stages) that were most likely retained consistently by the net are underlined in Table 1. Data for some other taxa are not quantitative because of the effects of sampling and preservation. These taxa include the gelatinous zooplankton (ie. cnidarian medusae and larvaceans). The sample splitting process also affects estimates of thecosomate pteropods because they do not stay suspended in the sample.

ACKNOWLEDGMENTS

We thank Shailey Cummings and David Nieman for their diligent work with the MOCNESS; Coreene Stewart for assisting with sample preservation; the staff at the sorting center in Szczecin, Poland; and the officers and crew aboard the NOAA ship Miller Freeman. We gratefully acknowledge Jay Clark for providing assistance on the cruise, with mapping programs and with ichthyoplankton data; Karen Conlan and staff for graphics; and Susan Fauska and her staff for final report preparation.
