Cover Photo: Image of a large male red king crab (*Paralithodes camschaticus*) taken with an underwater laser line scanning system at 78 fathoms (143 m) in Chiniak Bay near Kodiak. The crab is braced on his dactyls and is probing in the sediment. The feasibility of using an underwater laser for assessing fishing-related habitat impacts and resources was tested during a cooperative project between NMFS and ADF&G in the Fall of 1996.

RESULTS OF THE 1996 NMFS BERING SEA CRAB SURVEY EXECUTIVE SUMMARY

This section summarizes data presented in the Report to Industry on the 1996 Eastern Bering Sea Trawl Survey. Numbers presented are trawl survey indices of population level and do not necessarily represent absolute abundance. For further information, contact Dr. Robert Otto, NMFS, P.O. Box 1638, Kodiak, AK 99615. Phone (907) 487-5961. Guideline Harvest Levels (GHL) and landings were provided by the Alaska Department of Fish and Game. Landings are preliminary.

Red king crab (*Paralithodes camtschaticus*) Bristol Bay.

Legal males: 5.6 million crabs; 11% decrease.
Pre-recruits: 3.5 million crabs; 35% decrease.
Large females: 11.9 million crabs; 49% increase.
Outlook: Total population index continues at low levels. Fertilized female abundance is believed to be above threshold. The Alaska Department of Fish and Game's (ADF&G) length-based assessment model output indicated there was 5.3 million legal males and 10.2 million mature females. The fishery must be closed if fewer than 8.4 million fertilized females are on the grounds.
GHL: 5.0 million lbs (2,268 metric tons, mt). The Alaska Board of Fisheries' new policy calls for an exploitation rate of 10% of mature males under current stock conditions rather than 20% as in previous years. This fishery opened November 1st for the first time since 1993. Landings were 8.4 million lbs (3,810 mt).

Red king crab (*P. camtschaticus*) Pribilof District.

Legal males: 0.5 million crabs; 81% decrease.
Pre-recruits: <0.1 million crabs; 99% decrease.
Large females: 0.9 million crabs; 63% decrease.
Outlook: Legal and pre-recruit male crab are concentrated at few stations, and index has low precision. Females and small males are poorly estimated. Both survey and fishery data indicate population declines. Historically red king crab have been relatively rare in the Pribilof Islands and are usually harvested as incidental catch in the blue king crab fishery.
GHL: Fishery combined with blue king crab fishery in 1996; preliminary red king crab landings were 0.2 million lbs (91 mt).

Pribilof Islands blue king crab (*P. platypus*) Pribilof District.

Legal males: 1.2 million crabs; 40% decrease.
Pre-recruits: 0.7 million crabs; 37% decrease.
Large females: 4.6 million crabs; 15% decrease.
Outlook: Population low and stable. Trends not easily detectable.
GHL: 1.8 million lbs (816 mt) of red and blue king crab (see Page 1). Preliminary ADF&G data indicate 0.9 million lbs (408 mt) of blue king crab were taken in the September fishery.

St. Matthew blue king crab (*P. platypus*) Northern District.

Legal males: 3.4 million crabs; 76% increase.
Pre-recruits: 2.0 million crabs; 78% increase.
Large females: Not well estimated.
Outlook: Population at above long-term average levels. Rocky grounds preclude surveying important portions of the habitat. Survey abundance may be affected by year-to-year changes in the portion of the stock available to the survey.
GHL: 4.3 million lbs (1,950 mt). Preliminary ADF&G data indicate that 3.0 million lbs (1,361 mt) were landed in the September fishery.

Tanner crab (*Chionoecetes bairdi*) Eastern District.

Legal males: 9.1 million crabs; 8% decrease.
Pre-recruits: 23.5 million crabs; 27% decrease.
Large females: 27.7 million crabs; 26% decrease.
Outlook: Population still declining; little sign of recruitment as a once large cohort continues to decay.
GHL: 6.2 million lbs (2,812 mt). Fishery opened November 1st. Preliminary data indicate that only 1.8 million lbs (816 mt) were landed.

Snow crab (*C. opilio*) All districts combined.

Large males: 172 million crabs; 149% increase.
Small males: 2,700.0 million crabs; 34% decrease.
Large females: 1,364.0 million crabs; 43% decrease.
Outlook: Large crab enter the commercial fishery at 102 mm carapace width although the legal size is 78 mm. Anticipated recruitment to the commercial size male population has evidently occurred and will continue into 1997. The sharp drop in abundance of small crab may indicate poor recruitment on the horizon.
GHL: 117.0 million lbs (53,070 mt). Fishery opened January 15, 1997. Landings data are not yet available.

Hair crab (*Erimacrus isenbeckii*)

Total males: 8.4 million crabs; 24% decrease.
Large females: Not well estimated.
Outlook: Population at about average levels; recruitment trends not apparent.
GHL: 0.9 million lbs (408 mt), Pribilof District only. Fishery opened November 1st. Landings were 0.7 million lbs (310 mt).

THE 1996 EASTERN BERING SEA SURVEY

The National Marine Fisheries Service (NMFS) conducts an annual trawl survey in the eastern Bering Sea (EBS) to determine the distribution and abundance of crab and groundfish resources. This report summarizes survey results for commercially important crabs. It is intended to aid the fishing industry in locating productive grounds and judging overall availability of various species. Survey-derived data are also used as part of the basis for management decisions. Results are presented for red king crab (*Paralithodes camtschaticus*), blue king crab (*P. platypus*), hair crab (*Erimacrus isenbeckii*), Tanner crab (*Chionoecetes bairdi*) and snow crab (*C. opilio*). Information on groundfish resources is available from the Alaska Fisheries Science Center, 7600 Sand Point Way NE, BIN C15700, Seattle, Washington 98115.

Landing statistics for 1996 are preliminary data obtained from the Alaska Department of Fish and Game (Skip Gish, ADF&G, Dutch Harbor, personal communication). Those needing final statistics should contact ADF&G directly.

Survey Area and Methods

The 1996 EBS crab survey consisted of 375 successful bottom trawl tows and covered an area of approximately 139,200 square nautical miles (nmi). This year's survey area (Fig. 1) was nearly identical to that of 1995. The survey was conducted aboard two chartered vessels, the *F/V Aldebaran* and *F/V Arcturus*, between June 8 and July 28. The same vessels were used in 1993, 1994 and 1995. Methodology was identical to that of previous surveys and most tows were made at the centers of squares defined by a 20x20 nmi grid. Near St. Matthew Island and the Pribilofs, additional tows were made at the corners of squares.

Both vessels fished an eastern otter

trawl with an 83 ft headrope and a 112 ft footrope. This has been the standard trawl since 1982. Wingspread on this trawl ranges from 47-58 ft. For consistency with previous reports an effective width of 50 ft was assumed. Each tow was one-half hour in duration; average length was 1.50 nmi. Crabs were sorted by species and sex, and then a sample of crabs was measured (to the nearest millimeter) to provide a size-frequency distribution. Crab sizes are reported as carapace width (cw) for Tanner and snow crabs, and carapace length (cl) for all others. Procedures for estimating abundance were similar to previous years (Appendix A). Note that population estimates are indexes and are most precise for large crabs; however, they may not represent absolute abundance and are least precise for females and small crab due to vagaries in crab behavior and net performance.

Because of differences in the length of each tow, catches presented in accompanying charts and tables are standardized to the nearest whole number of crab caught per square nmi. Where more than one tow was made in a square (including corner tows), charts indicate average crab density for all tows. Tables 7-11 present data for all tows where each species was caught, without averaging. It is advisable to cross-reference charts and tables.

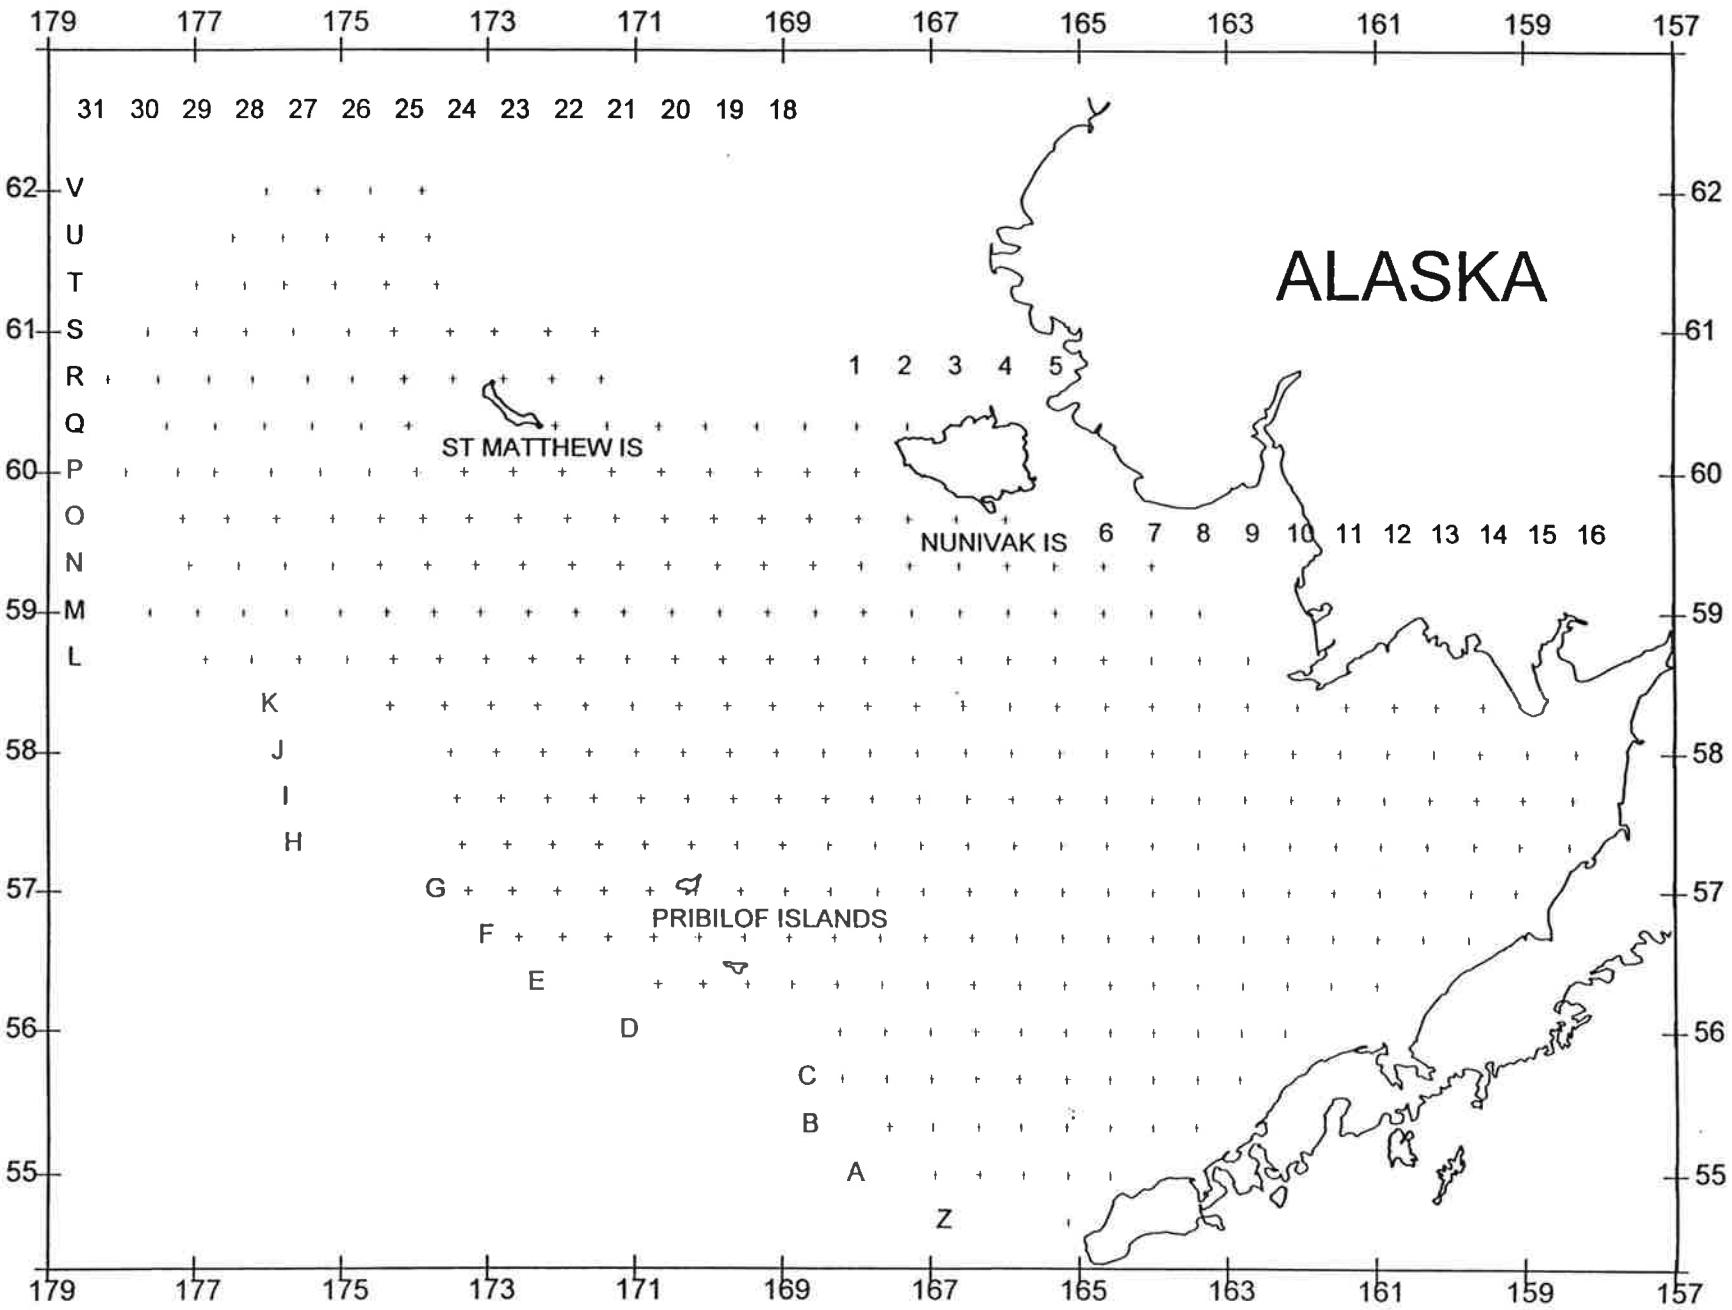

The following abbreviations are used in the text: (in) inches, (mm) millimeters, (fm) fathoms, (lbs) pounds, ($^{\circ}$ C) degrees Celsius, (cl) carapace length, and (cw) carapace width.

Distribution and Abundance of Crab Stocks

Bristol Bay Red King Crab (*P. camtschaticus*)

Legal-sized (≥ 6.5 in cw or 135 mm cl) male crabs were distributed evenly throughout central Bristol Bay (Chart 1 and Table 7).

FIGURE 1. NMFS eastern Bering Sea crab survey area in 1996.

Red King Crab
Bristol Bay Statistical Area

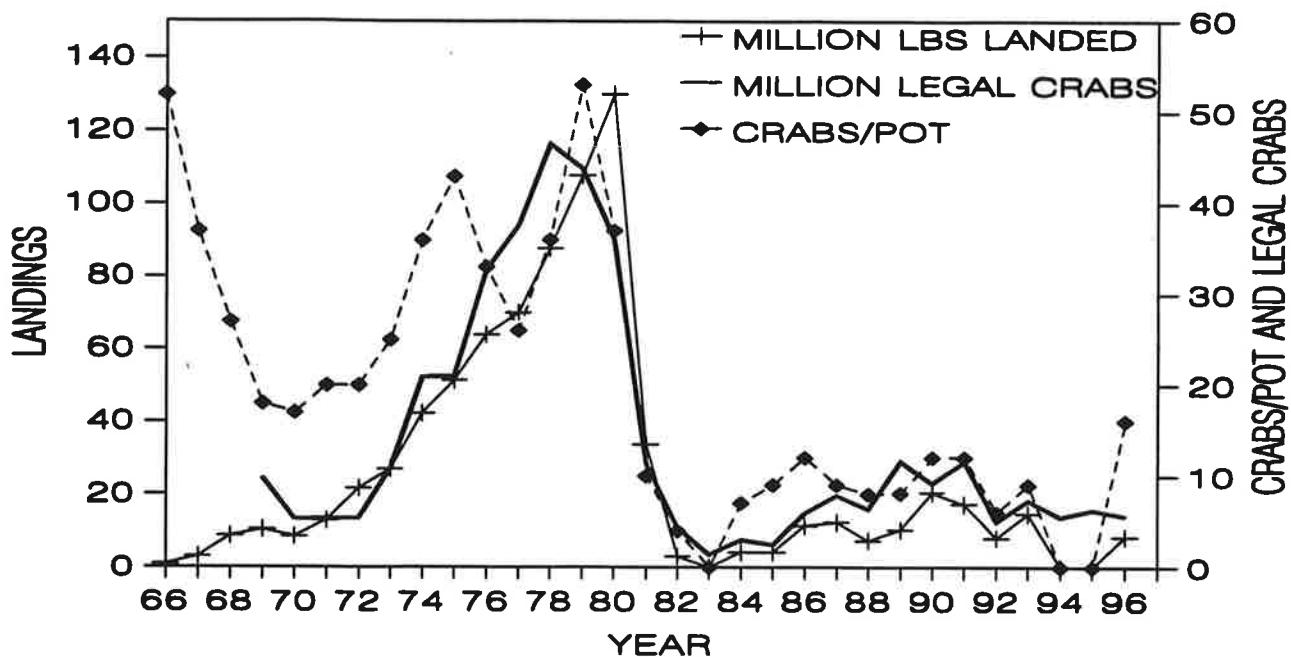

FIGURE 2. U.S. landings in millions of pounds, CPUE as crabs per pot, and abundance of legal red king crab (*P. camtschaticus*) in millions in Bristol Bay, estimated from NMFS trawl surveys (abundance data include the Pribilof District prior to 1983).

The abundance index of legal male red king crabs in the Bristol Bay District (south of 58°39'N and east of 168°W) was 5.6 million crabs (Table 1 and Fig. 2). The estimate represents an 11% decrease from last year and is significantly below the 25-year average (13.1 million). Pre-recruit crab (110-134 mm cl) at 3.5 million showed a decrease of 35%. Abundance of juveniles increased by 79%. A mode observed at a mean size of 55 mm cl in 1994 grew to a mean size of 75 mm in 1995 (Fig. 3) and to about 88 mm in 1996. The abundance index for total males is still very low. The fishable stock will probably continue to decline in 1997 but may increase thereafter as juveniles grow and recruit to the fishery. About 5% of legal male crabs were in molting or soft-shell condition, and 55% were oldshell crabs (Appendix B).

The abundance index for large (≥ 90 mm cl) females in Bristol Bay was 11.9 million crabs. This was an increase of 49% relative to 1995 and resulted in opening of the fishery

for the first time since 1993 (see below). Females are showing a recruitment pattern similar to males. In June, 21% of sampled mature females were still molting or soft-shell (vs. 35% last year). Among sampled mature females, the proportion which had molted and extruded new, uneyed eggs was 98% compared with 82% last year. Fluctuations in the timing of molting, mating, and embryo extrusion may be related to annual variations in water temperature.

The length-based assessment (LBA) model, developed by ADF&G, was fitted to the survey time series in order to evaluate the abundance of mature females relative to the threshold and to establish a GHL (ADF&G Regional Information Report 5596-12). ADF&G evaluations using the LBA model gave values of 10.2 million mature (≥ 90 mm cl) females, 4.3 million pre-recruit males (110-134 mm cl) and 5.3 million legal males. Model results were, hence, very similar to survey results. The new Alaska Board of Fisheries

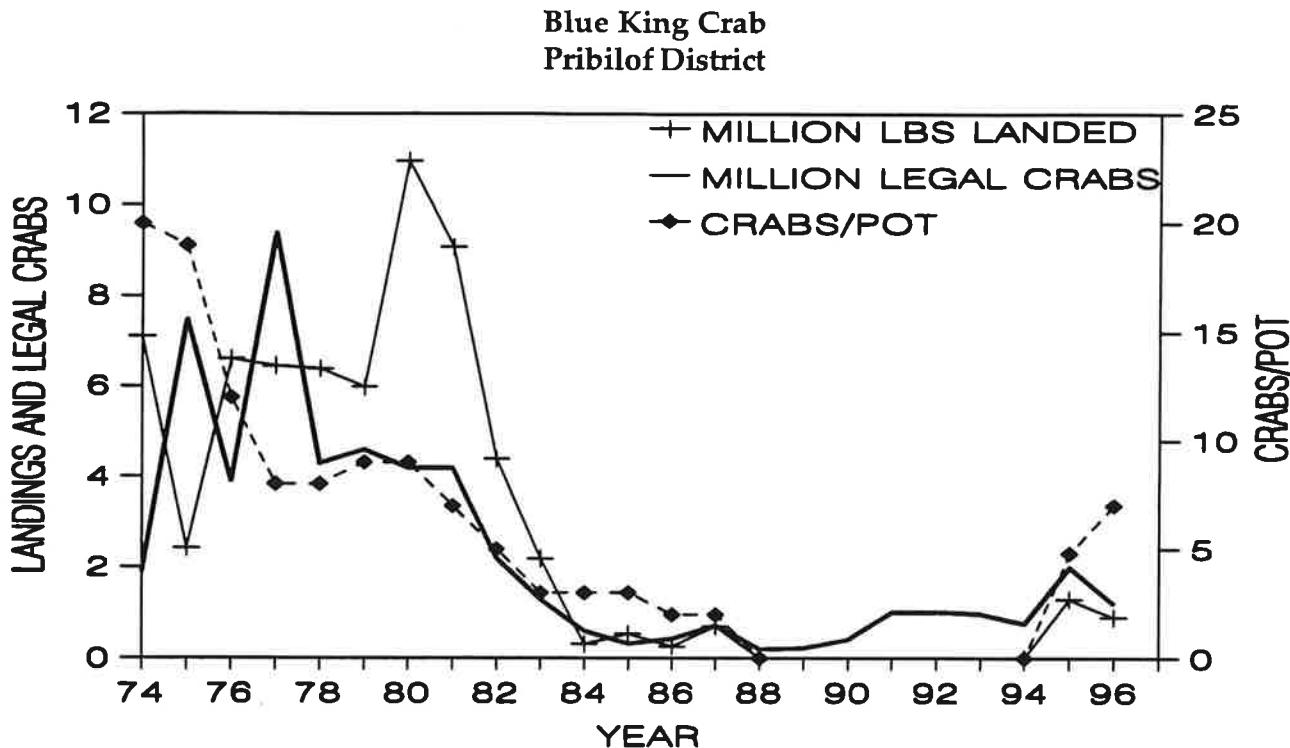

FIGURE 4. U.S. landings in millions of pounds, CPUE as crabs/pot, and abundance of legal blue king crab (*P. platypus*) in millions in the Pribilof District, estimated from NMFS trawl surveys.

policy requires a harvest rate of 10% of mature males (> 119 mm cw) under current stock conditions as compared to 20% in previous fisheries.

The Bristol Bay fishery did not open in 1994 or 1995 because the index of fertilized females was below a threshold value of 8.4 million crabs (Appendix A). The index of fertilized female abundance is derived from the number of mature females adjusted for the proportions carrying full and partial clutches. The 1996 fishery was opened on November 1 with a GHL of 5.0 million lbs. The 1996 fishery lasted four days and produced 8.4 million lbs landed by 196 vessels with a CPUE of 16 crab/pot-lift.

Pribilof Islands Red King Crab

In the Pribilof District (south of 58° 39'N and west of 168° W), the abundance index for legal male red king crab was 0.5 million crabs, a decrease of 81% from last year's 2.6 million

crabs. Most of these crabs were quite large; the mean length was 174 mm cl as compared to 165 mm cl in 1995. The index for large females declined 62%. In previous years male crab were highly concentrated at one station (G21), which resulted in additional sampling. In 1996, no such "hot spot" was found. A combined fishery for red and blue king crab in the Pribilof District opened September 15 with a GHL of 1.8 million lbs of both species. Landings were 0.2 million lbs of red king crab with a CPUE of 0.4 crab/pot-lift.

Historically, red king crab have not been abundant in the Pribilof Islands and landings were taken incidentally during the blue king crab fishery. Red king crab were relatively abundant from 1992 to 1995 but now appear to be declining to a point where their abundance relative to blue king crab is similar to historical averages. Prior to 1992, the abundance of red king crab in the Pribilofs was nearly negligible.

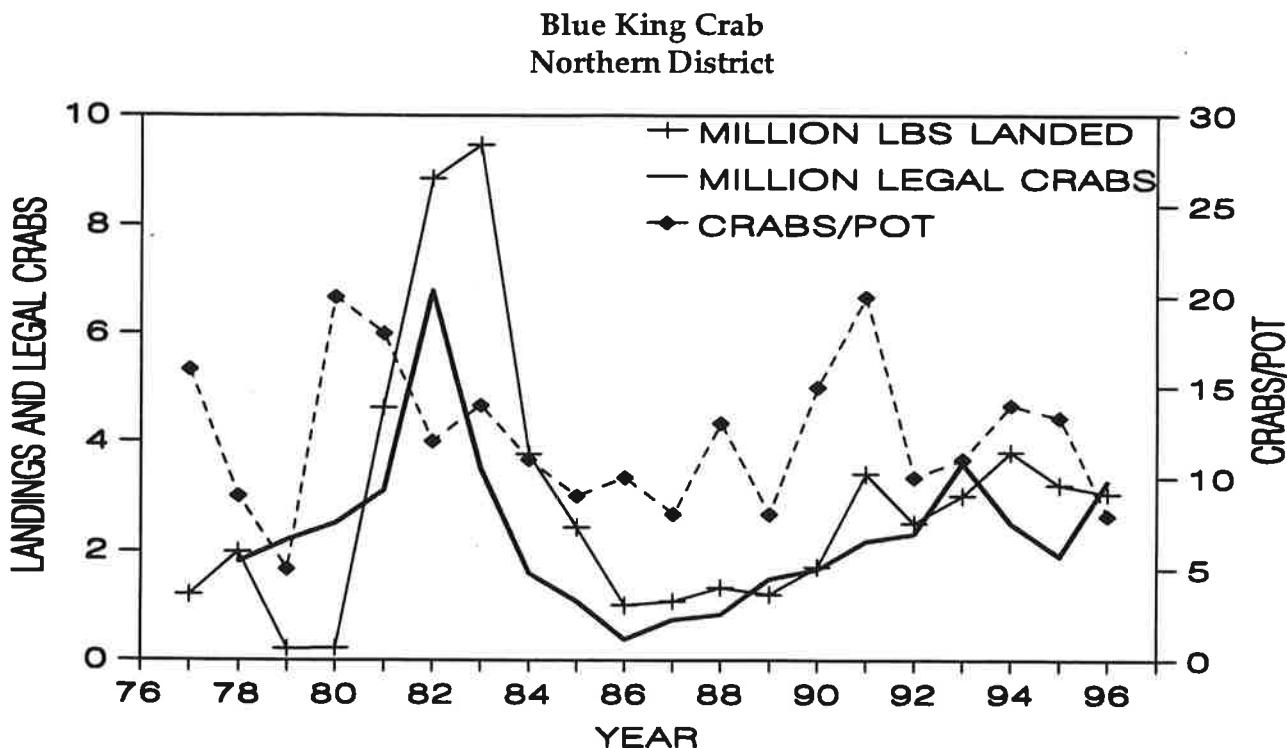

FIGURE 6. U.S. landings in millions of pounds, CPUE as crabs/pot, and the abundance of legal blue king crabs (*P. platypus*) in millions in the Northern District (St. Matthew Island), estimated from NMFS trawl surveys.

Pribilof Islands Blue King Crab (*P. platypus*)

Legal (≥ 6.5 in cw or 135 mm cl) males were found primarily north and east of St. Paul Island (Chart 2 and Table 8). The abundance index for legal males was 1.2 million crabs (Table 2 and Fig. 4), a 40% decrease from 1995, and is below the 22-year average (2.3 million). The number of pre-recruits (110–134 mm cl) also decreased 37% and the abundance of juveniles (<110 mm cl), showed a 58% decrease. Size-frequency data (Fig. 5) show decreases in all sizes of crab. Shell conditions among legal males were none soft or molting, 51% new-hardshells, and 49% oldshells, indicating that crabs were no longer molting during the survey.

The abundance index for large (≥ 90 mm cl) females showed little change from last year. However, estimates of juvenile and female abundance are usually very imprecise or biased due to the preference of such crab for rocky habitat which is not sampled well

by trawls. Among sampled mature females, 47% were new-hardshells, of which 99% carried new eggs, and 53% were oldshells, of which all carried empty embryo cases. Only one female carried a partial clutch of eyed eggs indicating hatching had recently occurred and was nearing completion. Blue king crab are predominantly biennial spawners. Only a portion of the female population spawns in a given year, while the remainder is in the non-embryo-bearing phase. No females had soft shells, indicating that molting was completed at the time of the survey.

This fishery was closed from 1987 through 1994 due to low stock abundance. In 1995, a combined fishery for red and blue king crabs was opened in the Pribilof District with a combined GHL of 2.5 million lbs and landings of 2.1 million lbs (1.3 million lbs were blue king crab). In 1996 the combined GHL was 1.8 million lbs and landings were 1.1 million lbs including 0.9 million lbs of blue king crab. CPUE was 4.8 blue king crab/pot-

*Too few crabs caught to estimate abundance.

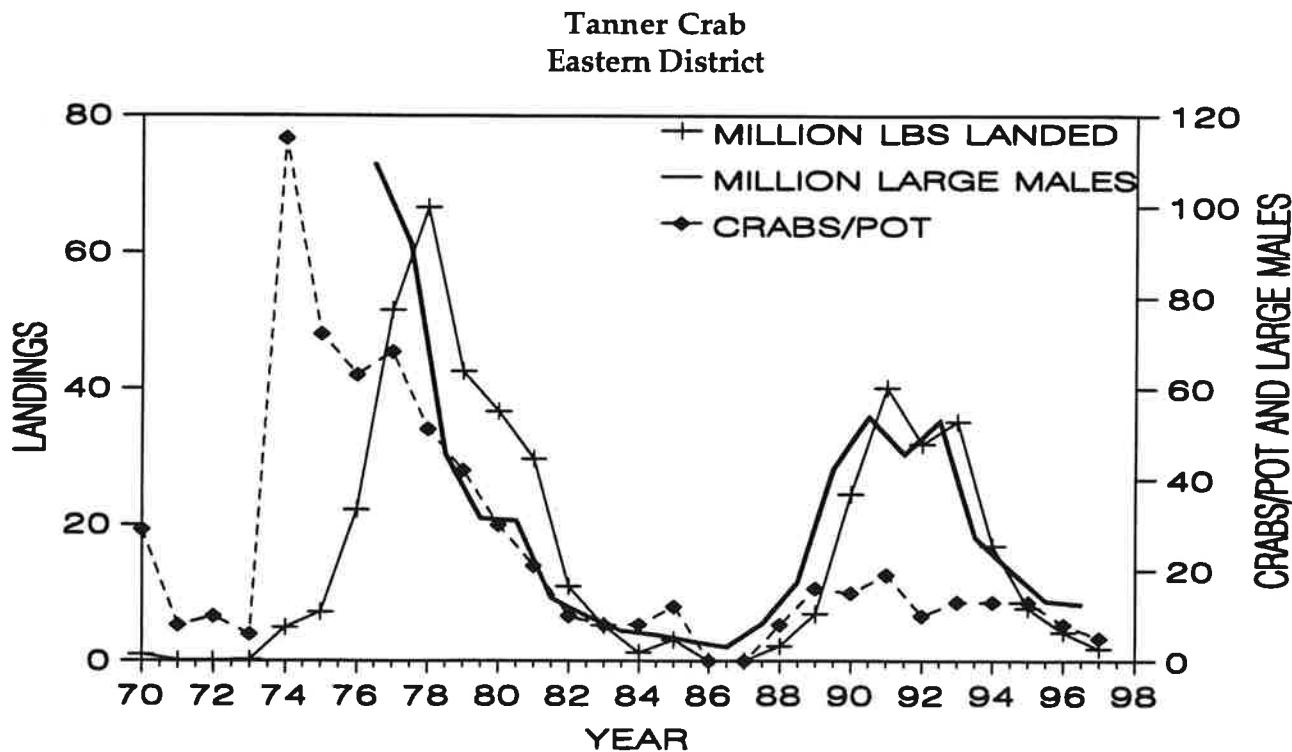

FIGURE 8. U.S. landings in millions of pounds, CPUE as crabs/pot, and the abundance of large male Tanner crab (*C. bairdi*) in millions in the Bristol Bay and Pribilof Districts (prior to 1989) or the Eastern District (since 1989), estimated from NMFS trawl surveys.

lift in 1995 and 6.7 crab/pot lift in 1996.

St. Matthew Island Blue King Crab (*P. platypus*)

Legal (≥ 5.5 in cw or 120 mm cl) males were captured primarily southwest of St. Matthew Island (Chart 2 and Table 8). The abundance index for legal males was 3.4 million crabs (Table 3 and Fig. 6), representing a 76% increase from last year. The abundance of pre-recruits (105-119 mm cl) showed a 78% increase. The distribution of size-frequencies is shown in Figure 7.

At 3.4 million crabs, the index of legal males is considerably above the long-term average of 2.25 million. Among legal males, 3% were softshell, 75% were new-hardshells, and 22% oldshells, similar to last year. The index for large females (≥ 80 mm cl) is poorly determined due to a habitat preference for inshore, rocky and untrawlable grounds. Only 38 mature females were captured.

The 1995 fishery opened on September

15 with GHL of 2.4 million lbs, landings of 3.2 million lbs and a CPUE of 13 crab/pot-lift (Fig. 6). Comparative figures for 1996 were a GHL of 4.3 million lbs, landings of 3.0 million lbs and CPUE of 7.9 crab/pot-lift.

Tanner Crab (*C. bairdi*)

The legal minimum size of 5.5 in cw (spine tip to spine tip) is equivalent to 138 mm cw measured between the spines (scientific measure). The data included in Table 4, however, define "large" crabs as males ≥ 135 mm, because this size has been used for a long-term index since 1976.

Legal males were widely distributed with regions of relatively high abundance in outer Bristol Bay (Chart 3 and Table 9). The abundance index for large (≥ 135 mm cw) male *C. bairdi* in the Eastern District (east of 173° W) is 12.5 million crabs (Table 4), of which 9.1 million are legal size (≥ 138 mm cw). Legal crab abundance decreased by 9% relative to 1995. About 26% of the legal crab were

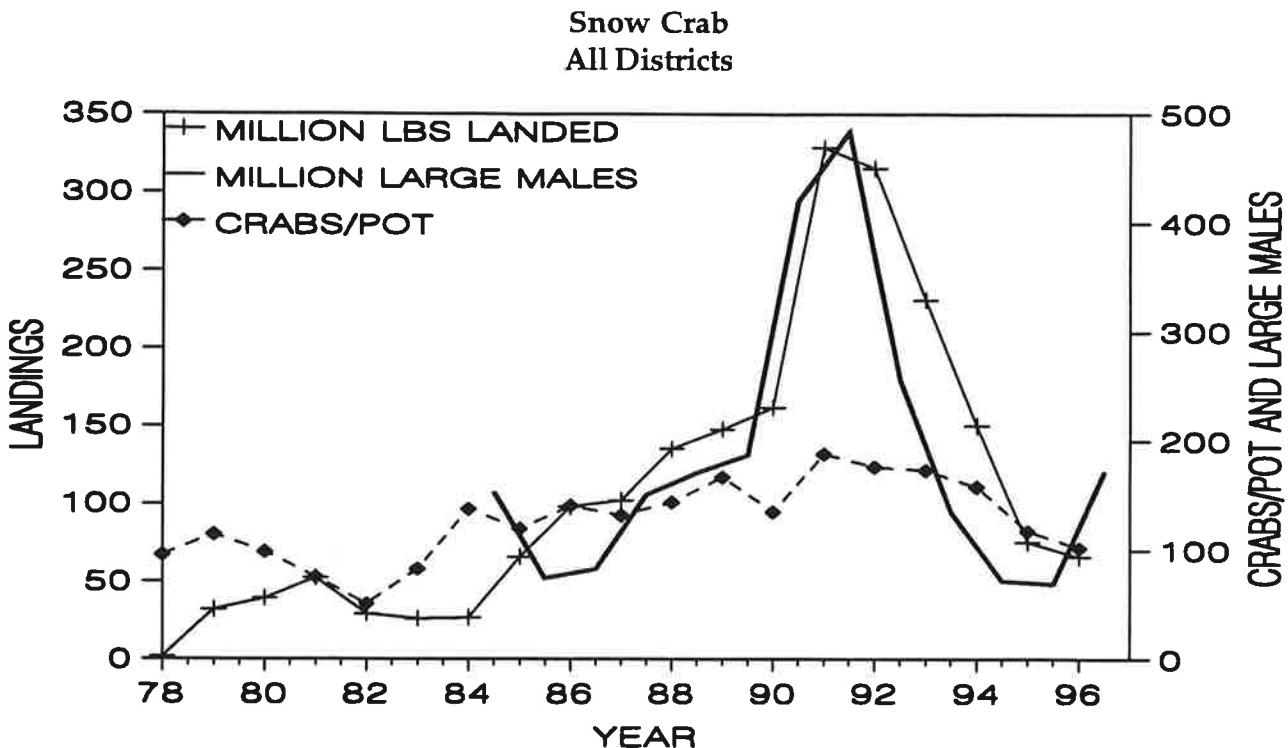

FIGURE 10. U.S. landings in millions of pounds, CPUE as crabs/pot, and the abundance of large male snow crab (*C. opilio*) in millions (all districts combined), estimated from NMFS trawl survey.

located east of 163°W , and virtually all the legal males occurred in the Eastern District. The abundance index for large crabs showed a decrease of 6% from last year (Table 4, Fig. 8) and is well below the 1975-1996 average (30.8 million). The abundance index for pre-recruits (110-134 mm cw) showed a 27% decrease and the index for small males (<110 mm cw) showed a 30% increase. A strong cohort of crabs which recruited to the fishery in 1988-1992 has declined due to natural mortality and fishery removals.

Low abundance of juveniles in the 45-115 mm cw range (Fig. 9) suggests that this population will continue to decline for several years.

As this population ages, the proportion of oldshell and very oldshell crabs has increased and that of newshell crabs decreased. Among large males, <1% were molting or softshell, only 2% were new-hardshells, and 98% were oldshells. Old shelled crab are not expected to molt again in their life spans.

Abundance of legal males will continue to decline over the next few years for this reason as well.

The abundance index of large (≥ 85 mm cw) females (all districts) showed a 25% decrease and the abundance of small (<85 mm) females also showed a 11% decrease from last year. Among sampled mature females, <1% were softshells; 10% were new-hardshells, of which 92% carried new eggs, and 90% were older shells, of which 66% carried new eggs. About 31% of mature females sampled had not completed spawning by the time of the survey.

In 1996, retention of Tanner crab was allowed during the Bristol Bay red king crab fishery and 0.9 million lbs were taken. Additionally, there was a GHL of 6.2 million lbs in the area west of 163°W which became available seven days after the Bristol Bay red king crab fishery closed. Only 0.9 million lbs of the GHL were taken and the fishery was closed due to its poor performance relative

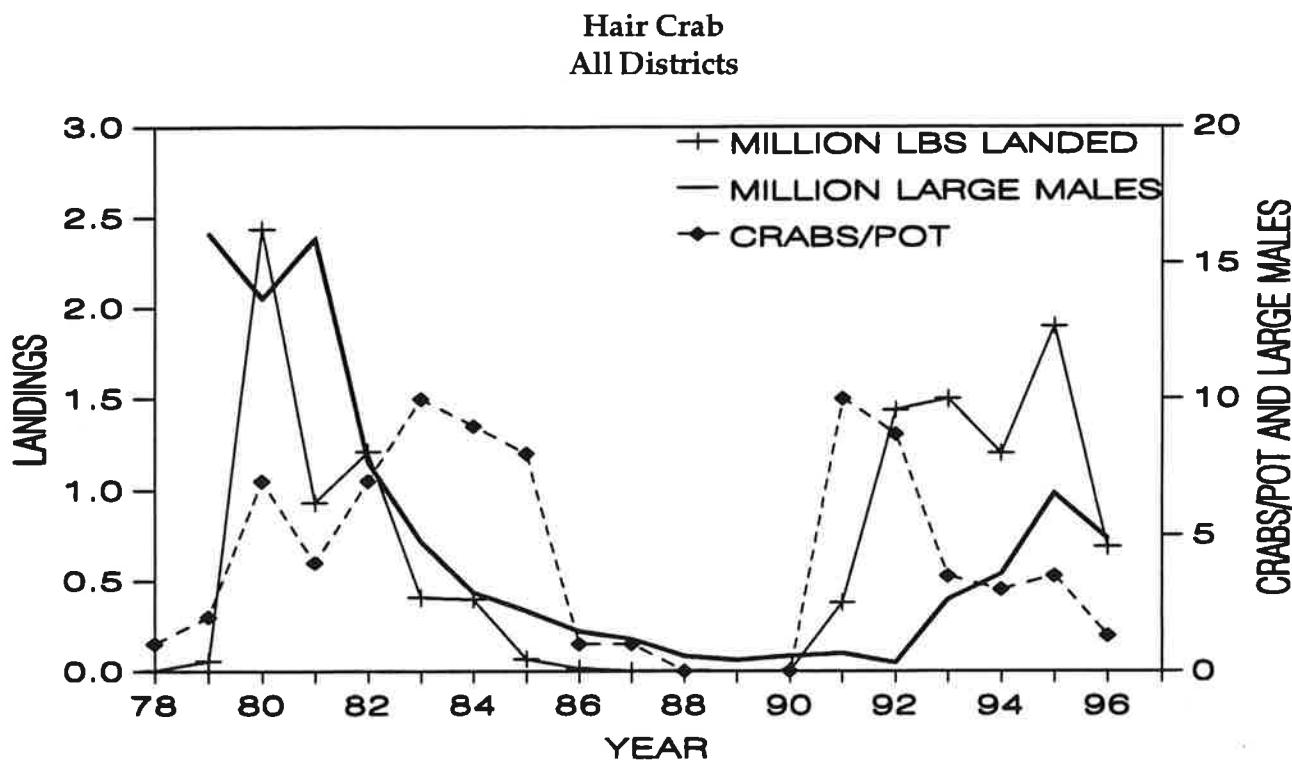

FIGURE 12. U.S. landings in millions of pounds, CPUE as crabs/pot, and the abundance of legal male hair crab (*E. isenbeckii*) in millions (all districts combined), estimated from NMFS trawl surveys.

to pre-season expectations. The 1996 CPUE was 5 crab/pot-lift as compared to 8 crab/pot-lift in 1995 (Fig. 8).

Snow Crab (*C. opilio*)

Although the legal minimum size limit for *C. opilio* is 3.1 in cw (78 mm), processors currently prefer a minimum size of 4.0 in cw (102 mm) and the mean size taken in the fishery is slightly above 110 mm cw. Therefore, the size ranges for male *C. opilio* used in this report are defined as follows: small, <4 in (102 mm); large, ≥4.0 in cw (102 mm); and very large ≥4.3 in cw (110 mm). Estimates of abundance of large males (≥4.0 in) are not shown prior to 1984 (Table 5 and Fig. 10) due to differences in area surveyed and minimum size landed. The 1996 abundance index for large males was 171.6 million as compared to 69 million in 1995 and the 1984-1996 average of 186.7 million.

The distribution of large males showed an area of high concentration extending north-

west and eastward from the Pribilof Islands (Chart 4 and Table 10). The abundance index for large (≥102 mm cw) males (Eastern and Western Districts combined) is 171.6 million crabs (Table 5), and represents a 149% increase from last year. Approximately 87% of these were in the Eastern District as compared to 60% in 1995. Small males (<102 mm cw) showed an 34% decrease. The abundance index for large females (≥50 mm cw) showed a 43% decrease.

The abundance of large males decreased from 1991-1995 due to natural mortality and fishery removals. However, good recruitment has occurred in the last few years and a large mode in the size-distribution is now entering the fishery (Fig. 11), possibly the result of a strong year class hatched in the period 1988-1990. Continued recruitment to the large size category should offset losses due to fishing and mortality in 1998. This growth should lead to a stable abundance of large males next year but the lack of very small

* Estimates not available at present time.

crabs may indicate declining abundance over a longer term.

Among large male crabs, 27% were in molting or softshell condition, 61% were new-hardshells indicating a recent molt, and 12% were oldshells. Among sampled mature females, 39% were new-hardshells, of which 99% carried new eggs, and 61% were oldshells, of which 93% carried new eggs. These numbers indicate that hatching and extrusion were nearly completed by the time of the survey.

The GHL for 1997 has been set at 117.0 million lbs for large crab (≥ 4.0 in cw). The fishery opened at noon on January 15. In 1996 the GHL was 55.7 million lbs, landings were 66 million lbs and the average CPUE was 102 crab/pot-lift (Fig. 10).

Hair Crab (*Erimacrus isenbeckii*)

Hair crab are widely scattered across the EBS (Chart 5 and Table 11). Historically, areas of concentration have existed just north of the Alaska Peninsula and near the Pribilof Islands. We have never found many female or small male crab during the survey and hence, have little understanding of their distribution. The abundance index for large male hair crabs declined from 1981-1992 but has generally increased since 1992 (Fig. 12). The current index of 8.4 million total males (Table 6) represents a 24% decrease during the past year but is similar to the 1980-1996 average (8.2 million). The abundance index of 4.9 million large (≥ 3.25 in cw) males is similarly 26% lower than last year. The abundance index of total females shows an increase of 52% from last year, but is unreliable and based on capture of only 42 crabs. Size-frequency data (Fig. 13) indicate that the large cohort first seen in 1989-90 is maturing and recruitment of juveniles is decreasing. Changes in abundance indexes of hair crab are difficult to interpret due to patchy distribution, burying habits, inshore distribution and suspected variability in catchability between years. Further, changes in fishery practices and management over the time series decreases the usefulness

of correlations between fishery and survey data. The majority of males (80%) and females (81%) were new-hardshell crabs.

The directed fishery for hair crab in the Pribilof Islands has no minimum legal size, so we have defined large crabs equivalent to the industry-preferred minimum size of 3.25 cw. Currently there are an estimated 4.4 million lbs of large male crab in the Pribilof District. A GHL of 0.9 million lbs was set for the Pribilof District in 1996 and 0.7 million lbs were taken by 21 vessels. CPUE was 1.3 crab/pot-lift. Landings in 1995 were 1.89 million lbs, with CPUE of 3.4 crab/pot-lift (Fig. 12).

Acknowledgements

Successful completion of the annual EBS crab and groundfish survey is crucially dependent on the skipper and crews of the participating vessels. We wish to extend a special thanks to Glenn Sullivan and John Ploeger of the *F/V Arcturus* (listed as Vessel #88 in Tables 7-11) and Kenneth Disrude and Norman Bakken of the *F/V Aldebaran* (listed as Vessel #89 in Tables 7-11) and their crews.

APPENDIX A

Methods of Estimating Crab Population Size

Population abundance indices are determined by the 'area-swept' method, using a stratified systematic sampling design. Distance traveled by the trawl was determined from positions recorded at the beginning and ending of the trawl. Area fished (= area swept by the trawl) was calculated by multiplying the distance by the effective width of the trawl, assumed to equal 50 ft.

All stations (grid squares) within a district or management area were used for estimating the abundance of each species. Stations where multiple (corner or repeat) tows were made were grouped into strata; these include a block of 12 stations southwest of St. Matthew Island and 16 stations around St. Paul Island.

The catch-per-unit-effort (CPUE) was calculated for each station as number of crabs per square nautical mile. Average CPUE was calculated within each multiple tow block and each management district. Abundance indi-

ces were calculated by extrapolating the average CPUE of each size/sex group over the geographic area of each district. Variance and standard error (SE) of the index were calculated arithmetically. Confidence intervals were calculated by adding or subtracting 2 SEs to the population estimate. Note that, since the data are usually not normally distributed, variance estimates and confidence intervals are approximate. Nevertheless, they are provided in order to indicate the range of the data relative to previous years' estimates.

Threshold levels have been established for certain crab stocks by the Crab Plan Team of The North Pacific Fishery Management Council. In accordance with Alaska Board of Fisheries policy, and the Alaska Department of Fish and Game's Management Plan for Westward Region Crab stocks, such fisheries will be closed if the abundance index falls below the threshold level.

APPENDIX B

Crab Shell Condition

All crabs measured in the NMFS eastern Bering Sea trawl survey are coded as to shell condition. Shell condition categorizes exoskeleton discoloration, scratching and wear, and fouling by encrusting organisms, and can be used to estimate the time since a crab has last molted. The shell condition categories used in this report and the estimated times since last molting that they imply are given below:

Molting¹: Joints swollen and/or well developed second exoskeleton present. Crab will molt within days or is actively molting.

Softshell¹: Carapace is still soft and pliable from recent molt. Crab has molted within weeks.

New, hardshell: Carapace firm to hard and lacking scratches, wear, discoloration, and en-

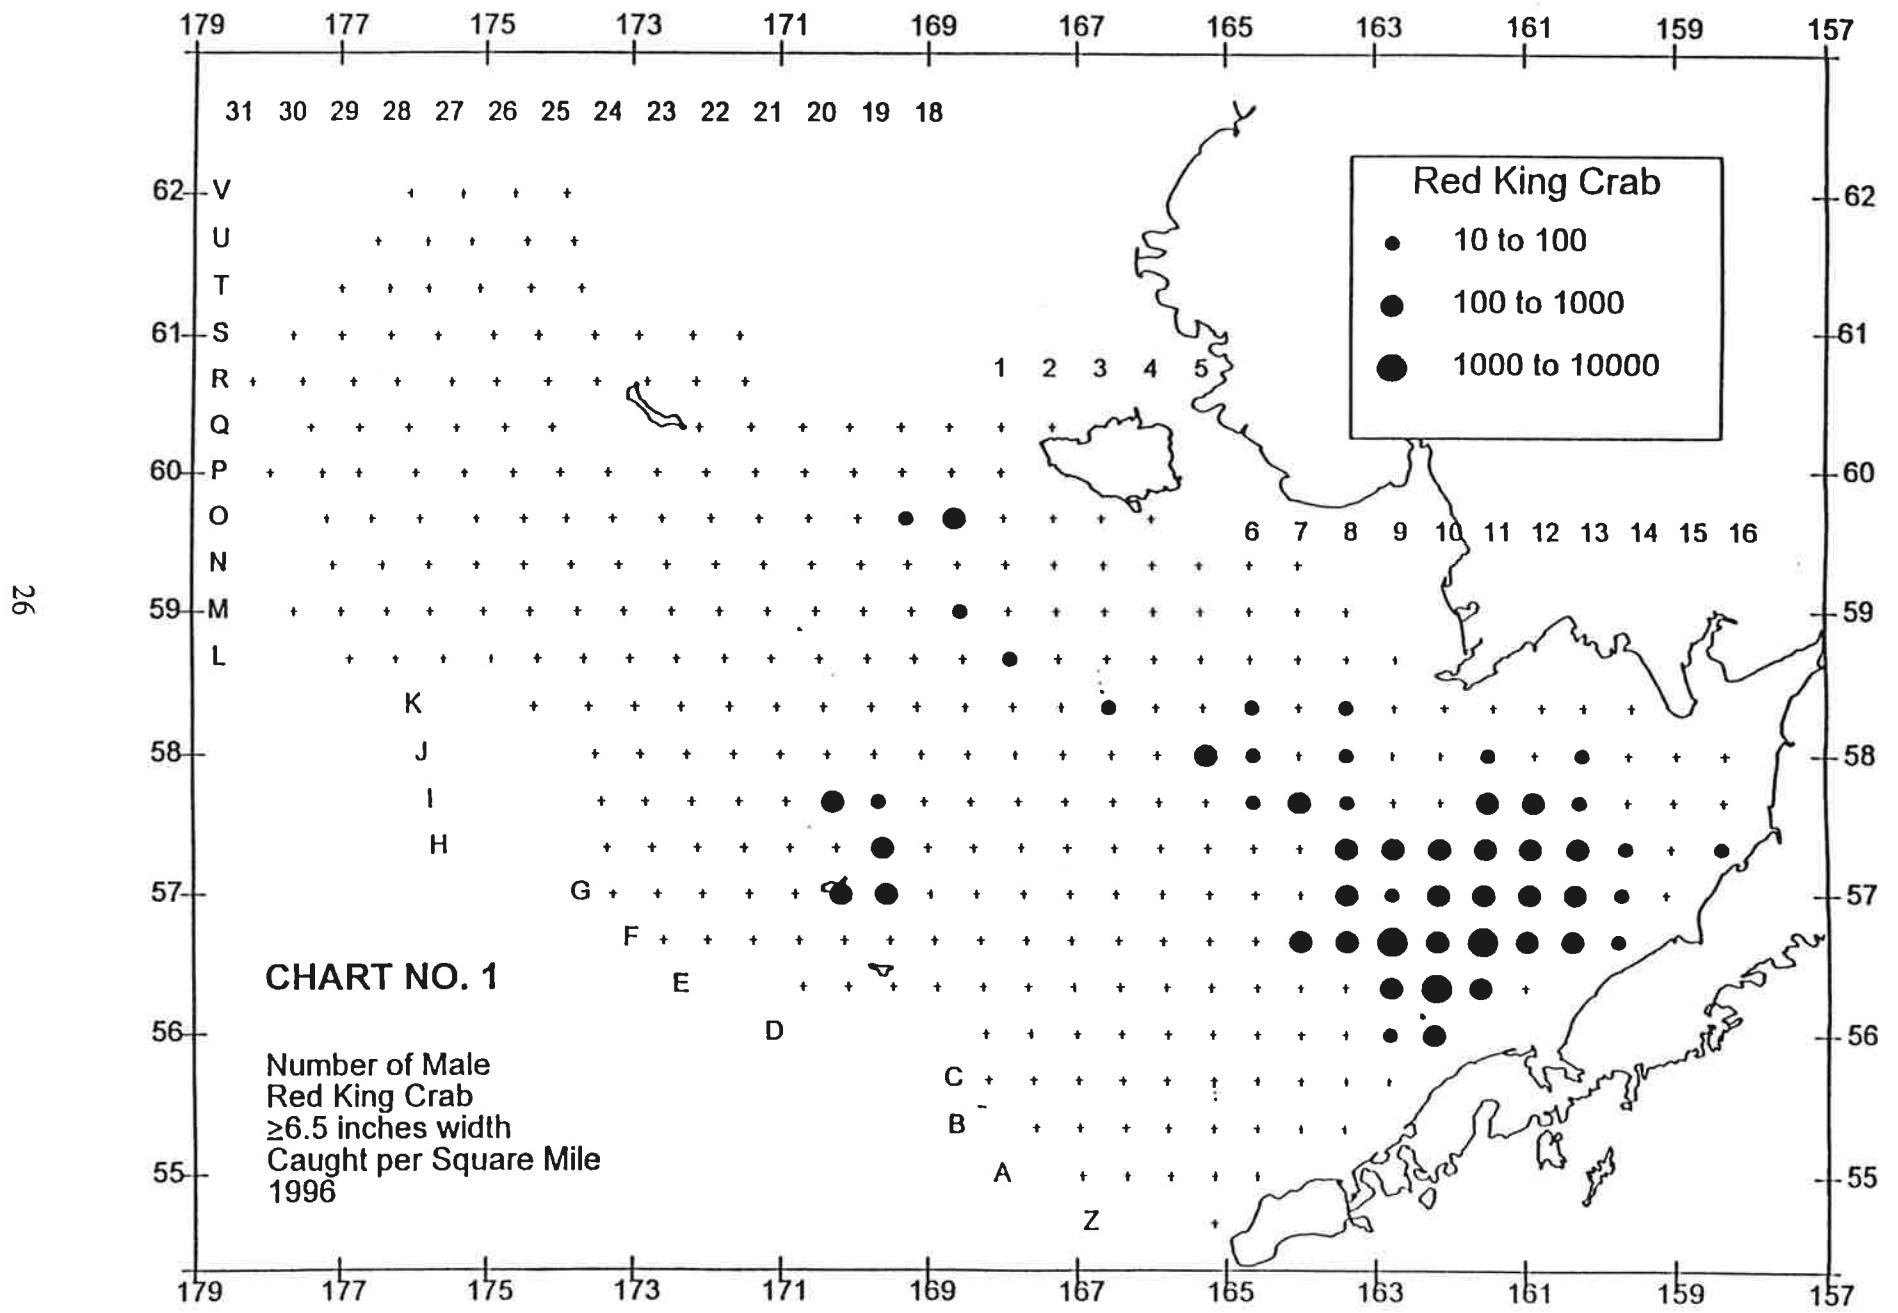

crusting organisms. Crab has probably molted within the last year.

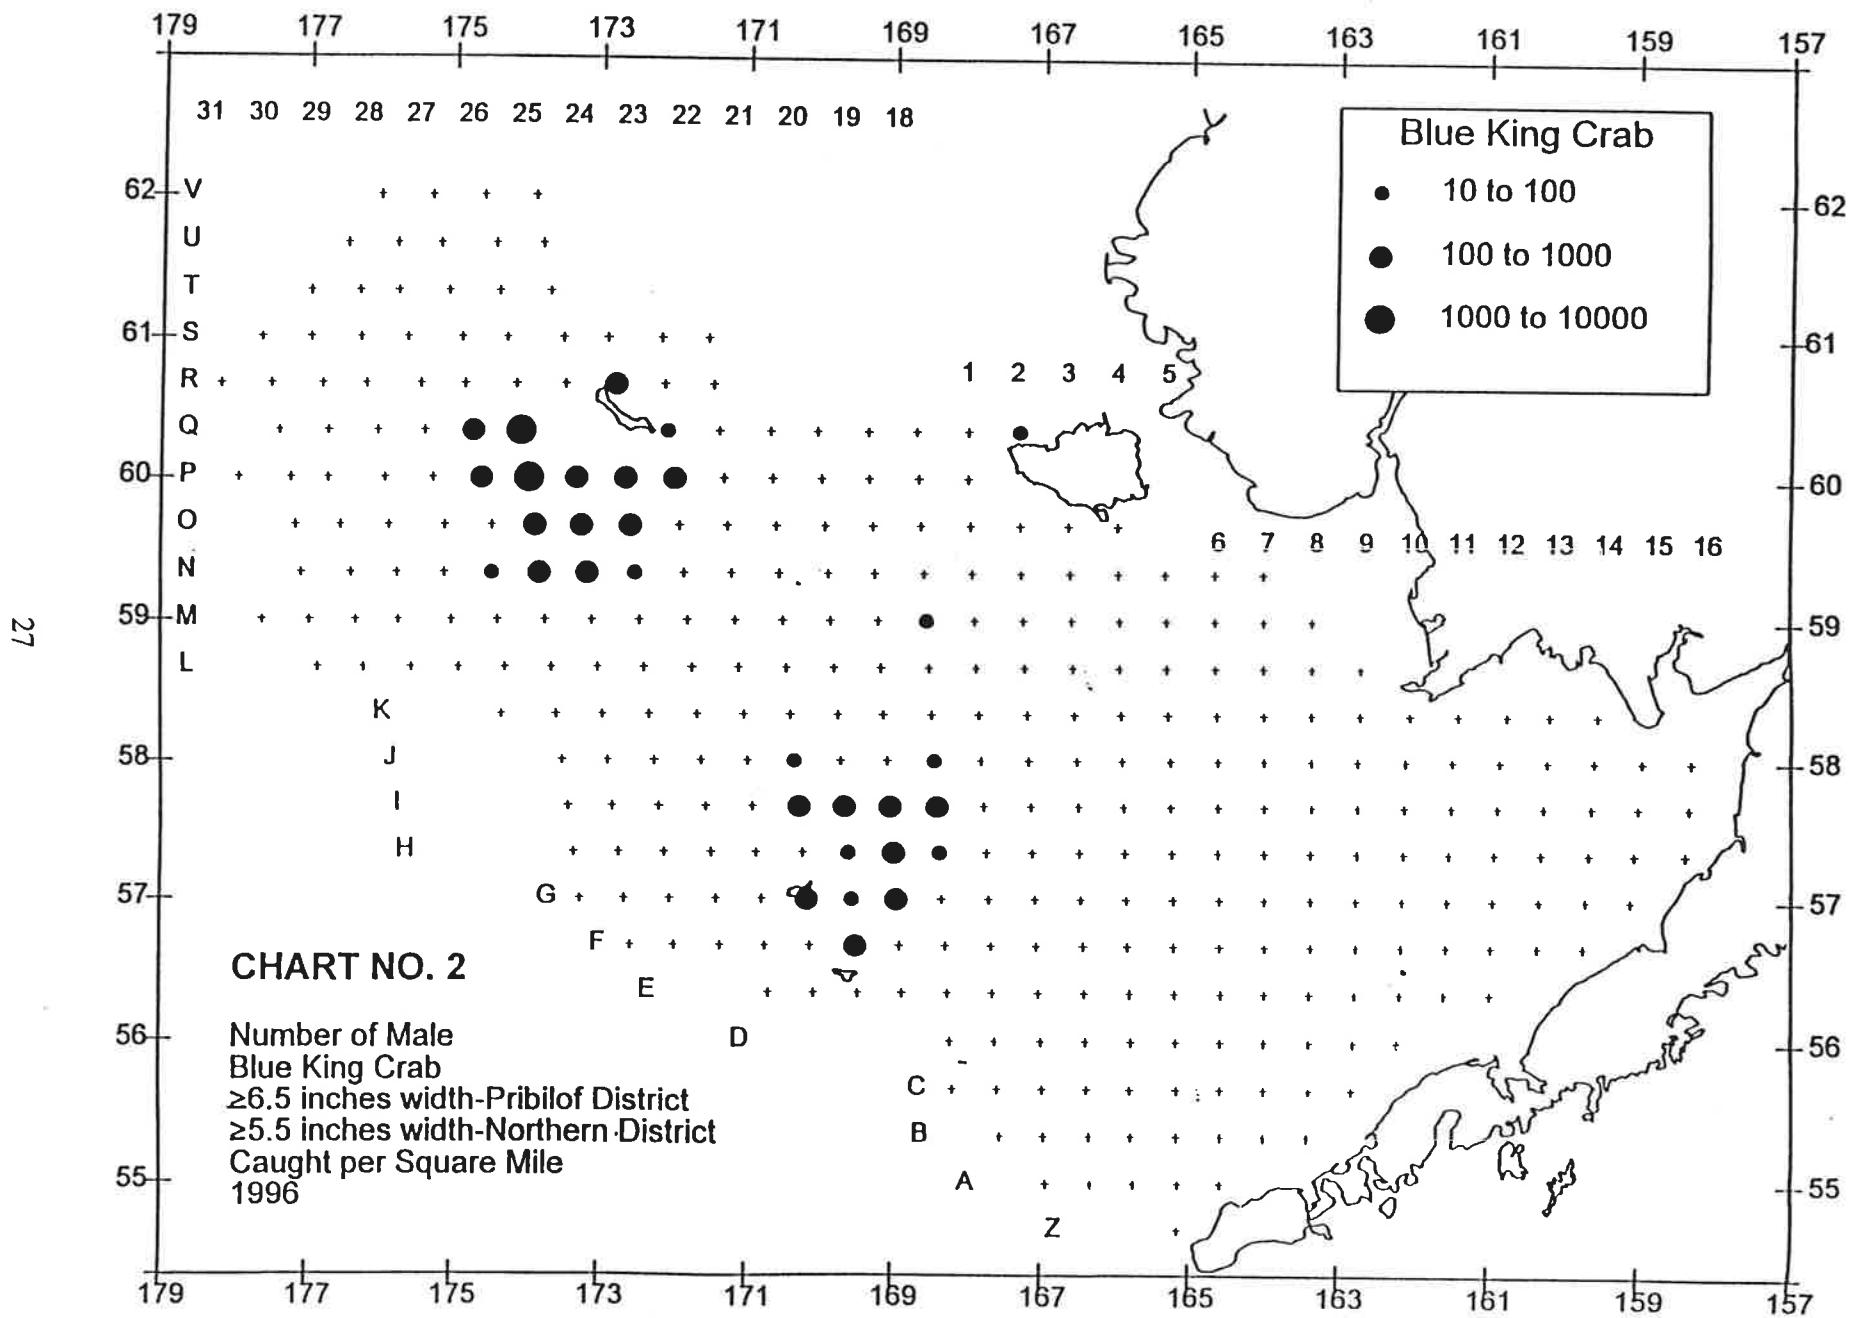

Oldshell: Usually has at least some scratching, spine wear. Crab may have darker coloration, and encrusting organisms are frequently present. Crab has probably not molted within the last year.

Very oldshell: Undersides of legs yellowed; abundant scratches and stains; spines and claws very worn; encrusting organisms almost always present and often abundant. Time since the last molting is almost certainly greater than one year but not definitely known.

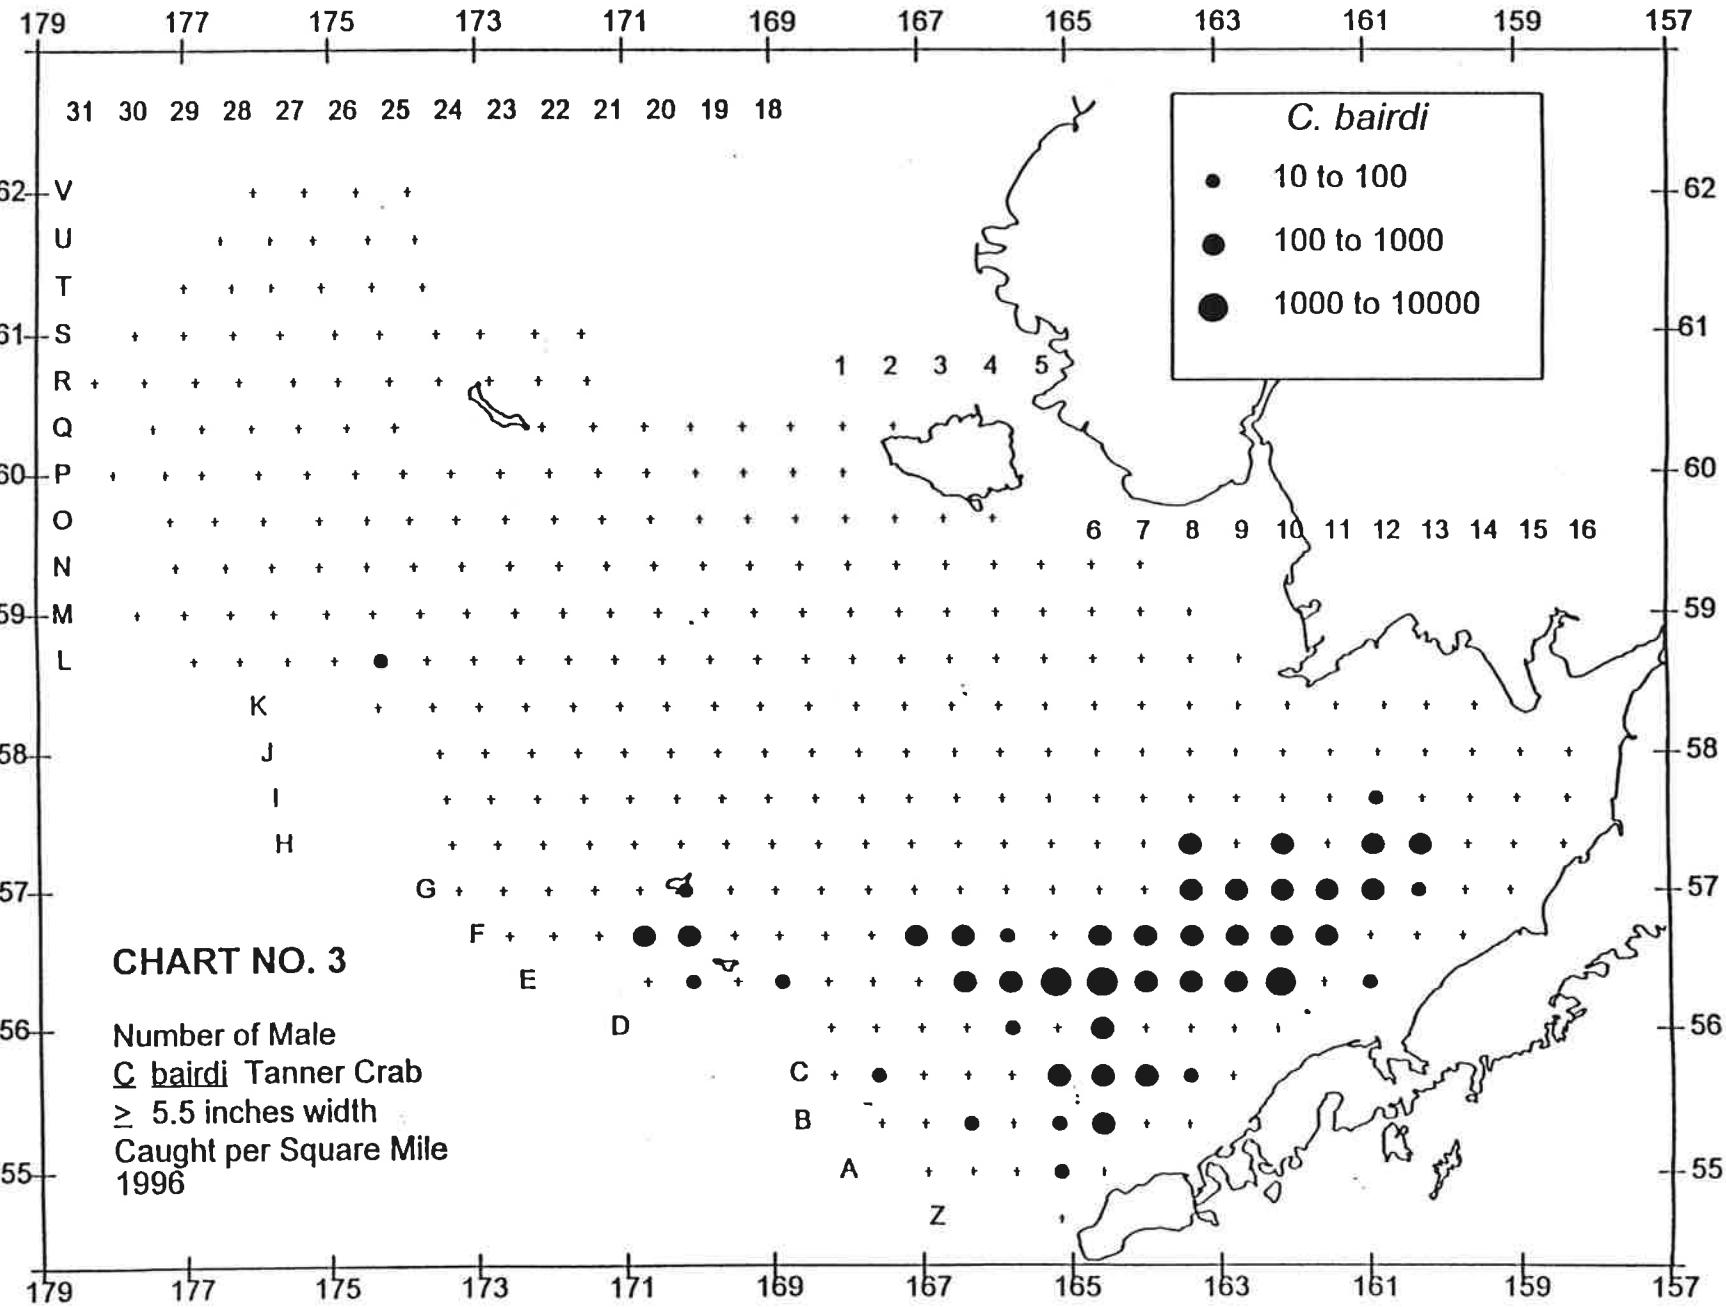

Very, very oldshell: Shells extensively stained and usually with extensive cover of encrusting organisms. Time since the last molting not definitely known.

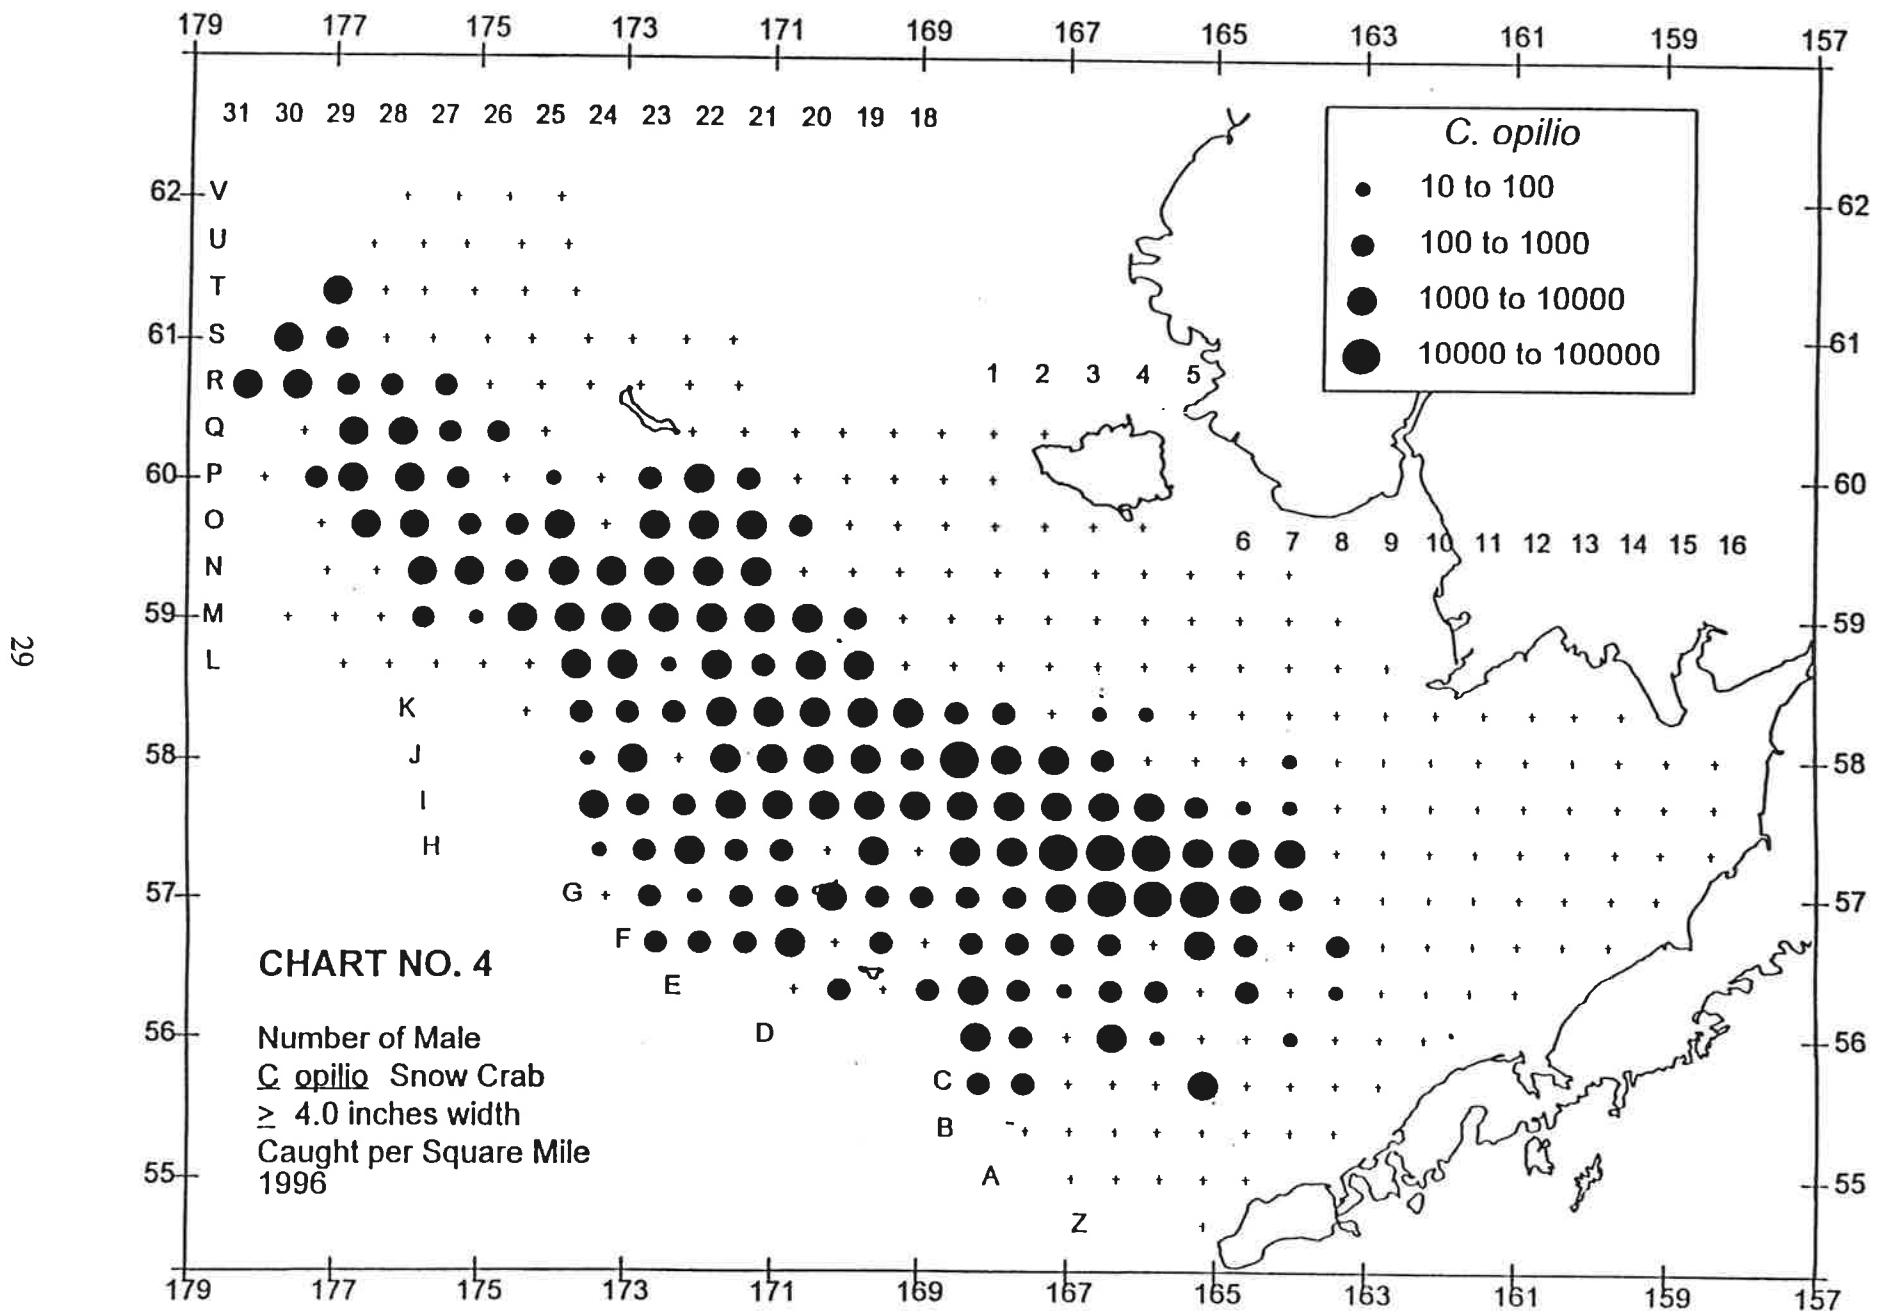

¹ Note that in the report, Molting and Softshell categories are frequently combined. The time span over which these conditions occur in a crab is only a matter of weeks. A high percentage of molting and softshell crabs in a survey population indicates that the molting season is not yet over.

28
