

5. Assessment of the Deepwater Flatfish Stock Complex in the Gulf of Alaska

Carey R. McGilliard and Wayne Palsson
November 2017

Executive Summary

Introduction

The Gulf of Alaska deepwater flatfish complex (consisting of Dover sole, Greenland turbot, and deepsea sole) is assessed every four years and was last assessed in 2015. In other years, we present an executive summary to recommend harvest levels for the next two years. Please refer to the 2015 full stock assessment report for further information regarding the assessment model (McGilliard and Palsson, 2015, available online at <http://www.afsc.noaa.gov/REFM/Docs/2015/GOAdeepflat.pdf>). A full stock assessment document with updated assessment and projection model results will be presented in 2019.

Dover sole is assessed using an age-structured model and Tier 3 determination. Thus, the single species projection model was run using parameter values from the accepted 2015 Dover sole assessment model (McGilliard and Palsson 2015), together with updated catch information for 2015-2017, to predict stock status for Dover sole in 2018 and 2019 and to make ABC recommendations for those years. Projections are conducted using numbers-at-age for Dover sole from age 3-59+ and historical recruitment of age 3 individuals is used to calculate OFL's and ABC's. Greenland turbot and deepsea sole fall under Tier 6. ABC's and OFL's for Tier 6 species are based on historical catch levels (average catch over the years 1978-1995) and therefore these quantities cannot be updated. ABC's and OFL's for the individual species in the deepwater flatfish complex are determined only as an intermediate step for the purpose of calculating complex-level OFL's and ABC's.

Summary of Results

As in previous years (McGilliard 2016), the species-level ABC is 179 t for Greenland turbot and the OFL is 238 t for both 2018 and 2019. The species-level ABC for deepsea sole is 4 t and the OFL is 6 t for both 2018 and 2019. The species-level ABC for Dover sole is 9,202 t in 2018 and 9,316 t in 2019 and the OFL is 11,050 t in 2018 and 11,187 t in 2019.

Based on the updated projection model results, the recommended complex-level ABC's for 2018 and 2019 are 9,385 t and 9,499 t, and the OFL's are 11,294 t and 11,431 t. The new ABC recommendation and OFL for 2017 are similar to those developed in 2016 (9,382 t and 11,290 t). The principal reference values are shown in the following table:

Species	Quantity	As estimated or specified last year for:		As estimated or recommended this year for:	
		2017	2018	2018*	2019*
Dover sole	<i>M</i> (natural mortality rate)	0.085	0.085	0.085	0.085
	Tier	3a	3a	3a	3a
	Projected total (3+) biomass (t)	143,333	144,611	144,654	145,899
	Projected Female spawning biomass (t)	49,331	49,347	49,366	49,373

	Status	As determined in 2016 for:		As determined in 2017 for:	
		2015	2016	2016	2017
	Overfishing	no	n/a	no	n/a
	Overfished	n/a	no	n/a	no
Approaching overfished	n/a	no	n/a	no	

*Projections are based on estimated catches of 232 t and 265 t used in place of maximum permissible ABC for 2017 and 2018-2019, respectively. The 2017 projected catch was calculated as the current catch as of October 8, 2017 added to the average October 8 – December 31 catches over the 5 previous years. The 2018-2019 projected catch was calculated as the average catch over the previous 5 years.

Area Apportionment

Area apportionment for ABC of deepwater flatfish is currently based on the proportion of survey biomass of Greenland Turbot and deepsea sole found within each management area from 2001-2017 and an estimate of 2018-2019 survey biomass for Dover sole in each management area based on results from the random effects model. An ABC exists only at the level of the complex (deepwater flatfish) and not for each species individually. The ABC by area for the deepwater flatfish complex is then the sum of the species-specific portions of the ABC.

The random effects model is used to fill in depth and area gaps in the Dover sole survey biomass by area and to calculate an area- and depth-specific estimate of 2018 and 2019 survey biomass. These estimates are summed over depths and the resulting relative biomass in each management area is used as the basis for apportionment of the Dover sole portion of the deepwater complex. This method of conducting area apportionment for deepwater flatfish was recommended by the GOA Plan Team in 2016 (McGilliard 2016). The method was chosen because it accounts for time and area gaps in the survey for Dover sole, which comprises nearly all of the deepwater flatfish catch and moves to deeper waters ontogenetically, and explicitly accounts for differences in the spatial distributions of Dover sole and Greenland turbot. Greenland turbot were found exclusively in the Western region by the survey over the period 2001-2015.

Species	Year	West				Total
		Western	Central	Yakutat	Southeast	
Dover Sole		2.5%	36.9%	35.2%	25.3%	100.0%
	2018	234	3,397	3,238	2,332	9,202
	2019	237	3,439	3,278	2,361	9,316
Greenland Turbot		100.0%	0.0%	0.0%	0.0%	100.0%
	2018	179	0	0	0	179
	2019	179	0	0	0	179
Deepsea Sole		0.7%	72.9%	15.3%	11.0%	100.0%
	2018	0	3	1	0	4
	2019	0	3	1	0	4
Deepwater Flatfish	2018	413	3,400	3,239	2,332	9,385
	2019	416	3,442	3,279	2,361	9,499

Figures

Figure 1. Catch:total biomass ratio using total biomass for age 3+ individuals for Dover sole only.

Tables

Table 1. Total catch of Dover sole, deepsea sole, and Greenland turbot and for the deepwater flatfish complex in total. Catch for 2017 is current up to October 8, 2017.

Year	Dover Sole	Deepsea Sole	Greenland Turbot	Total
