Pelagic Shelf Rockfish

by

David M. Clausen, Chris R. Lunsford, Dana H. Hanselman and Jeffrey T. Fujioka

November 2003

10.0 Executive Summary

Data from the 2003 Gulf of Alaska trawl survey were incorporated into this year's assessment, which results in new estimates of current exploitable biomass and new values of ABC, ABC geographic apportionment, and overfishing for 2004. These values are summarized as follows:

1. An average of the 1999, 2001, and 2003 surveys was used to compute the estimate of current exploitable biomass for the assemblage, 60,754 mt. This estimate is composed of 53,719 mt of light dusky rockfish, 975 mt of dark dusky rockfish, 187 mt of widow rockfish, and 5,874 mt of yellowtail rockfish.

2. ABC for dusky rockfish was computed similar to previous years, in which an F=M=0.09 strategy was used. This F is more conservative than the maximum allowable for a tier 4 species such as dusky rockfish because trawl survey biomass estimates and abundance trends for this species are very uncertain. Multiplying the current exploitable biomass for dusky rockfish (including both light and dark forms), 54,694 mt, by 0.09 yields an ABC of 4,922 mt for this species in 2004. ABC for widow and yellowtail rockfish was computed based upon the maximum allowable F for tier 5 species, 0.75 x M. Multiplying the current exploitable biomass for widow and yellowtail rockfish, 6,061, by 0.75 times an M of 0.09 yields an ABC of 409 mt. Total Gulfwide ABC for the assemblage in 2004 is the addition of these two ABC values: 5,330 mt.

3. Recommended geographic apportionment of this ABC was calculated using the same procedure as in previous years, in which a 4:6:9 weighting of biomass in the three most recent trawl surveys (i.e., 1999, 2001, and 2003) was used to compute distribution of biomass by area. The calculated biomass distribution was 8.3% in the Western area, 67.4% in the Central area, and 24.4% in the Eastern area. The recommended apportionments for 2004 are: Western area, 440 mt; Central area, 3,590 mt, and Eastern area, 1,300 mt. The Eastern area ABC is further apportioned into West Yakutat, 730 mt, and East Yakutat/Southeast Outside, 570 mt, based on a computed distribution of 56% in West Yakutat and 44% in East Yakutat/Southeast Outside.

4. Based on the tier 4 status for dusky rockfish and the tier 5 status for widow and yellowtail rockfish, the overfishing level was computed to be 7,440 mt for dusky rockfish and 545 mt for widow and yellowtail rockfish, which totals 7,980 mt for the entire assemblage.

5. Minor additions to the report include these data for light dusky rockfish in the Gulf of Alaska: lengths from the 2002 commercial fishery, age compositions from the 2001 trawl survey, and length compositions from the 2003 trawl survey.

Summary of Major Changes
A major addition to the assessment this year is Appendix A, which discusses results of an age-structured model for light dusky rockfish and presents alternative values of exploitable biomass and ABC for this species. If this alternative approach is accepted by the Plan Team, this would move light dusky rockfish from tier 4 to tier 3 in the NPFMC's overfishing definitions. In 2002, a working age-structured base model for light dusky rockfish was developed, and this model was presented at the November 2002 Plan Team Meetings In 2003, substantial refinements were made to the base model, and all data available through 2003 were incorporated. The model estimate of total biomass is 50,376 mt and next year's spawning biomass, B_{2004} is 16,157 mt. The model indicates the 2004 Gulfwide ABC for light dusky rockfish based on an $F_{40\%}$ harvest rate (0.123) is 4,000 mt. Using the same apportionment procedure described in item #3 above, geographic apportionment of this ABC is: Western area 330 mt, Central area 2,690 mt, and Eastern area 980 mt. The Eastern area can be further apportioned into West Yakutat, 550 mt, and East Yakutat/Southeast Outside, 430 mt. Note that if the model results are used to calculate ABC, these results only apply to light dusky rockfish, and that ABC's for dark dusky, widow, and yellowtail rockfish will have to be added to the values for light dusky rockfish to determine the ABC's for the entire assemblage.

Responses to SSC comments
There were no SSC comments.

10.1 INTRODUCTION

The pelagic shelf rockfish assemblage in the Gulf of Alaska is comprised of three species: dusky rockfish (*Sebastes ciliatus*), yellowtail rockfish (*S. flavidus*), and widow rockfish (*S. entomelas*). Pelagic shelf rockfish can be defined as those species of *Sebastes* that inhabit waters of the continental shelf of the Gulf of Alaska, and that typically exhibit a midwater, schooling behavior. Gulfwide, dusky rockfish is the most important species in the assemblage, whereas yellowtail and widow rockfish are generally considered minor species in Alaska waters.

Dusky rockfish has one of the most northerly distributions of all rockfish species in the Pacific. It ranges from southern British Columbia north to the Bering Sea and west to Hokkaido Is., Japan, but appears to be abundant only in the Gulf of Alaska. No studies have been done to determine if the Gulf of Alaska population is one stock, or if subpopulations occur.

The taxonomy of dusky rockfish is unclear, and biochemical studies (Seeb 1986 and footnote[1]) and morphometric studies[2] indicate that two distinct species of dusky rockfish likely occur in the Gulf of Alaska: an inshore, shallow water, dark-colored variety; and a lighter-colored variety found in deeper water offshore. No actual reclassification of dusky rockfish has yet been made, but a publication is currently in preparation that will propose the formal separation of the two varieties into distinct species[3].

[1]Seeb, L.W. 2000. Molecular markers distinguish light and dark forms of the dusky rockfish (*S. ciliatus*) in the Gulf of Alaska. Presentation at the 11th Western Groundfish Conference, Sitka, Alaska, April 25-28, 2000.

[2]Orr, J.W., and J. Blackburn. 2000. Morphology and systematics of dusky rockfish: the *Sebastes ciliatus* problem. Presentation at the 11th Western Groundfish Conference, Sitka, Alaska, April 25-28, 2000.

[3]J. Orr, National Marine Fisheries Service, Alaska Fisheries Science Center, RACE Division, 7600 Sand Point Way NE, BIN C15700, Seattle, WA 98115-0070. Pers. commun. October 2000.

In this report, nearly all the discussion on dusky rockfish will concern the offshore, light-colored variety, since most information is available from offshore trawl surveys and the offshore commercial fishery.

Until 1998, black rockfish (*S. melanops*) and blue rockfish (*S. mystinus*) were also included in the assemblage. However, in April 1998, a NPFMC Gulf of Alaska Fishery Management Plan amendment went into effect that removed these two species from the federal management plan and transferred their jurisdiction to the state of Alaska..

10.2 FISHERY

10.2.1 Catch History

Fishery catch statistics for pelagic shelf rockfish in the Gulf of Alaska are only available for the years 1988-2003 (Table 10-1a). Previous to 1988, these fish were classified into another, larger management group ("other rockfish"), and it is generally not possible to separate out catches of the pelagic shelf species. Generally, annual catches increased from 1988 to 1992, and have fluctuated in the years following. This pattern is largely explained by management actions that have affected rockfish during this period. In the years before 1991, TAC's were relatively large for more desirable slope rockfish species such as Pacific ocean perch, and there was less reason for fishermen to target a lower valued fish such as dusky rockfish. However, as TAC's for slope rockfish became more restrictive in the early 1990's, there was a greater economic incentive for taking dusky rockfish. As a result, catches of the pelagic shelf assemblage increased, reaching 3,605 mt Gulfwide in 1992. In following years, in-season management regulations have usually prevented any further increase in the dusky rockfish fishery, and have sometimes caused a decrease in catch. For example, in 1997-1998 and 2000-2003, the pelagic shelf rockfish trawl fishery in the Central area was closed with a substantial amount of unharvested TAC remaining, either to ensure that catches did not exceed the TAC, or to prevent excessive bycatch of Pacific ocean perch or Pacific halibut.

It should be mentioned that the catches in Table 10-1a include black and blue rockfish for the years 1988-97, when these species were members of the pelagic shelf assemblage. A significant black rockfish jig fishery existed in the Gulf of Alaska starting in 1991, but precise catches of black rockfish for these years are not available. Clausen and Heifetz (1997) provided approximations of the Gulfwide annual catches of black rockfish for the years 1991-97. The approximation for 1997 was later revised in the 1998 SAFE report (Clausen and Heifetz 1998). These approximations can be subtracted from the Gulfwide totals in Table 10-1a to yield the following estimates of pelagic shelf rockfish catch for the three species that now comprise the assemblage:

Year	1991	1992	1993	1994	1995	1996	1997
Catch (mt)	1,773	3,163	3,041	2,610	2,342	1,834	2,280

Catches of pelagic shelf rockfish from research cruises since 1977 are listed in Table 10-1b.

10.2.2 Description of the Fishery

Pelagic shelf rockfish (excluding its former members black and blue rockfish) have been caught almost exclusively with bottom trawls. Species composition data for the present species in the assemblage are shown below for the fishery in the years 1991-2002, based on data from the domestic observer program:

	Percent of assemblage catch			
Year	Light dusky	Dark dusky	Yellowtail	Widow
1991	93.5	0.2	5.1	1.2
1992	98.9	0.3	trace	0.8
1993	98.1	trace	0.5	1.4
1994	98.3	1.2	0.1	0.4
1995	99.2	trace	trace	0.8
1996	99.7	trace	trace	0.3
1997	99.9	trace	trace	0.1
1998	99.9	trace	trace	trace
1999	97.4	2.6	trace	trace
2000	99.2	0.6	0.1	0.2
2001	99.7	0.3	trace	trace
2002	99.4	0.5	0.0	0.1

Although the vast majority of these catches come from bottom trawls, a small portion of the data may also come from longline vessels that carried observers, which could account for some of the yellowtail and dark dusky rockfish listed. Clearly, with the possible exception of 1991, nearly all the catch consists of "light" dusky rockfish.

The trawl fishery for light dusky rockfish in the Gulf of Alaska in recent years has occurred mostly in July, because management regulations do not allow rockfish trawling in the Gulf until the first week in July. The same trawlers that target Pacific ocean perch and northern rockfish also target light dusky rockfish. Typically, these vessels fill the quota first for Pacific ocean perch, and after this fishery is closed, move on to catch dusky and northern rockfish. Catches of light dusky rockfish are concentrated at a number of relatively shallow, offshore banks of the outer continental shelf, especially the “W” grounds west of Yakutat, Portlock Bank northeast of Kodiak Is, and around Albatross Bank south of Kodiak Is. Highest catch-per-unit-effort in the commercial fishery is generally at depths of 100-149 m (Reuter 1999). During the period 1988-95, almost all the catch of light dusky rockfish (>95%) was taken by large factory trawlers that processed the fish at sea. This changed starting in 1996, when smaller shore-based trawlers also began taking a sizeable portion of the catch in the Central area for delivery to processing plants in Kodiak. These shore-based trawlers have accounted for the following percentages of the trawl catch in the Central area in the years 1996-2002[4]:

1996	1997	1998	1999	2000	2001	2002
27.1	18.1	25.0	45.2	74.4	58.0	49.7

10.2.3 Bycatch

The only analysis of bycatch in rockfish fisheries of the Gulf of Alaska is that of Ackley and Heifetz (2001). They examined data from the observer program for the years 1994-96. For hauls targeting pelagic shelf rockfish, the major bycatch species were northern rockfish and fish in the “other slope

[4]National Marine Fisheries Service, Alaska Region, Fishery Management Section, P.O. Box 21668, Juneau, AK 99802-1688. Data are from weekly production and observer reports through October 5, 2002.

rockfish" management category, followed by Pacific ocean perch. Similarly, dusky rockfish was the major bycatch species for hauls targeting northern rockfish. These conclusions are supported by another study (Reuter 1999), in which catch data from the observer program showed dusky rockfish were most commonly associated with northern rockfish, Pacific ocean perch, and harlequin rockfish (the latter is one of the "other slope rockfish" species). There is no information on the bycatch of pelagic shelf rockfish in non-rockfish fisheries, but it is presumed to be small.

10.2.4 Discards

Fishery discard rates for pelagic shelf rockfish have been relatively low, as shown in the following table[5]:

Year	Discard rate (%)
1991	10.2
1992	5.9
1993	10.8
1994	9.4
1995	6.3
1996	10.9
1997	6.4
1998	4.8
1999	9.3
2000	3.8
2001	4.3
2002	4.7

In contrast, discard rates in the fisheries for slope rockfish in the Gulf of Alaska have generally been much higher (see chapters for Pacific ocean perch, northern rockfish, and shortraker/rougheye and "other slope rockfish" in this document).

10.3 DATA

10.3.1 Fishery Data

In addition to the catch data listed in Table 10-1a, length frequency data for dusky rockfish in the commercial fishery are also available for the years 1991-2002 (Figure 10-1). The reader is cautioned that for each year, these data are the raw length frequencies for all dusky rockfish measured by observers; because there was no attempt to collect or analyze these data systematically, some biases may be expected, especially for 1995 and 1996 when sample sizes were relatively small. Generally, however, these lengths were taken from hauls in which dusky rockfish was either the target or a dominant species, and they provide an indication of the trends in size composition for the fishery. Size of fish taken by the fishery generally appears to have increased after 1992; in particular, the mode increased from 42 cm in 1991-92 to 44-47 cm in 1993-97. The mode then decreased to 42 cm in 1998, and rose back to 45 cm in 1999-2002. Fish smaller than 40 cm are seen in moderate numbers in certain years (1991-92 and 1996-

[5] National Marine Fisheries Service, Alaska Region, P.O. 21668, Juneau, AK 99802. Data are from weekly production and observer reports through October 5, 2002.

98), but it is unknown if this is an artifact of observer sampling patterns, or if it shows true influxes of younger fish.

Age samples for light dusky rockfish have been collected by observers only in the 1999, 2000, and 2001 commercial fisheries. The 1999 and 2000 samples have not yet been aged, but aging has been completed for the 2001 samples (Figure 10-2). Similar to the fishery length data discussed in the preceding paragraph, the data in Figure 10-2 depicts the simple raw age distribution of the samples, and we did not attempt any further analysis to estimate a more comprehensive age composition. However, the samples were randomly collected from fish in over 100 hauls that had large catches of light dusky rockfish, so the raw distribution is probably representative of what the true age composition of the fishery would be. The fish ranged in age from 6 to 47 years. A mode was present at ages 13-15, which corresponds to the 1986-88 year classes.

10.3.2 Survey Data

10.3.2.1 Survey Biomass Estimates

Comprehensive trawl surveys were conducted on a triennial basis in the Gulf of Alaska in 1984, 1987, 1990, 1993, 1996, and 1999, and these surveys became biennial in 2001 and 2003. The surveys provide estimates of biomass for pelagic shelf rockfish (Table 10-2). It is important to note that the 2001 survey, in contrast to the previous surveys, did not cover the eastern Gulf of Alaska (the Yakutat and Southeastern statistical areas). Although the eastern Gulf was not sampled in 2001, in Table 10-2 we have included substitute estimates of 2001 biomass in this region for pelagic shelf rockfish. These substitutes were computed by averaging the biomass for each species in each area for the three previous surveys in 1993, 1996, and 1999. The estimates for the 1984 through 1996 surveys showed that dusky rockfish comprised virtually all the biomass of the assemblage. In 1999, dusky rockfish again predominated, but a relatively large biomass of yellowtail rockfish was also seen in the Southeastern area. This yellowtail rockfish biomass can be mostly attributed to one relatively large catch in Dixon Entrance near the U.S./Canada boundary. Dusky rockfish were separated into "light" or "dark" varieties only in the four most recent surveys in 1996, 1999, 2001, and 2003. Each of these surveys has shown that light dusky rockfish overwhelmingly predominate and that dark dusky rockfish are caught in small quantities. Presumably, the dusky rockfish biomass in previous surveys also consisted of nearly all light dusky rockfish. On a geographic basis, the Kodiak statistical area has usually shown the highest biomass of dusky rockfish. Biomass estimates for the assemblage have been consistently lowest in the Southeastern area, with the exception of 1999 when the large catch of yellowtail rockfish was found in this area.

Comparative biomass estimates for the seven triennial surveys show wide fluctuations in the abundance of dusky rockfish (Table 10-2; Figure 10-3). Total estimated biomass increased substantially between 1984 and 1987, dropped by over 50% in 1990, rebounded in 1993 and 1996, and decreased again in 1999 and in the areas that were sampled in 2001, and then increased in 2003. Large confidence intervals are associated with all these biomass estimates, particularly in 1987, 1996, and 2003, and are an indication of the generally patchy and highly aggregated distribution of this species. None of the changes in biomass appear to be statistically significant. Whether these fluctuations indicate true changes in abundance, temporal changes in the availability of dusky rockfish to the survey gear, or are an artifact of the imprecision of the survey for this species, is unknown. However, because of the apparently light fishing pressure on dusky rockfish during most of these years (catches have usually been much less than the ABC), and their relatively low rate of natural mortality (see section 10.4.1, "Assessment Parameters"), large and abrupt changes in abundance such as those shown by the trawl surveys seem unlikely.

10.3.2.2 Survey Size Compositions

Survey population size compositions suggest that recruitment of dusky rockfish is a relatively infrequent event, as only two surveys, 1993 and 2003, showed evidence of substantial recruitment (see Clausen and Heifetz 1989 for 1987 results and Figure 10-4 for 1990 through 2003 results). Size compositions of dusky rockfish from both the 1987 and 1990 surveys showed virtually no fish <35 cm. Mean population length increased from 39.8 cm in 1987 to 43.1 cm in 1990, apparently the result of growth. In 1993, however, a large number of small fish (~27-35 cm long) appeared which formed a sizeable percentage of the population, and this recruitment decreased the mean length to 38.3 cm. It is interesting to note, however, that no corresponding numbers of small fish are seen in the fishery length frequency data for this year (see Figure 10-1). In the 1996 and 1999 surveys, the length frequency distribution was similar to that of 1990, with very few small fish, and both years had a mean population length of 43.9 cm. The 2001 size composition, although not directly comparable to previous years because the eastern Gulf of Alaska was not sampled, shows modest recruitment of fish <40 cm. In 2003, a distinct mode of fish is seen at ~30 cm that suggests relatively strong recruitment may be occurring.

10.3.2.3 Survey Age Compositions

Gulfwide age composition data for dusky rockfish are available for the 1984 through 2001 trawl surveys. (Figure 10-5), and, similar to the length data, these age data also indicate that recruitment is highly variable. For each survey, ages were determined using the "break-and-burn" method of aging otoliths, and a Gulfwide age-length key was developed. The key was then used to estimate age composition of the dusky rockfish population in the Gulf of Alaska. The 1976 year class appeared to be abundant in the 1984 survey. This year class is also prominent in the 1987 and 1990 age compositions. In 1987, just 4 year classes (1975, 1976, 1977, and 1980) comprised over 75% of the estimated population, and mean age was 10.5 years. The 1990 results showed no significant recruitment of young fish and appeared to merely reflect growth of the population that existed in 1987; mean age was 14.4 years. The 1993 age composition showed a very prominent 1986 year class. This year class is clearly associated with the large influx of small fish that was noted previously in the 1993 size compositions, and its presence likely explains much of the increase in dusky rockfish biomass that year. The existence of a strong 1986 year class was further confirmed by the 1996 age composition, in which this year class was again the most important. The 1996 results showed little evidence of recruitment of young fish <10 years old; accordingly, mean age of the population increased from 12.1 years in 1993 to 14.7 years in 1996. In 1999, fish <10 years old again comprised only a small part of the population, and fish aged 12, which would correspond to the 1987 year class, were very prominent. Because rockfish are difficult to age, especially as the fish grow older, one possibility is that some of the fish aged 12 in 1999 were actually age 13 (members of the 1986 year class), which would agree more with the 1993 and 1996 age results. The 2001 age compositions show the 1986 year class is still discernable as a distinct mode at age 15. The 2001 data also indicated a possibly strong 1992 year class and that very few fish were >16 year old. Finally, it should be noted that the 2001 fishery age distributions discussed previously in section 10.3.1 agree with these survey age compositions, as they all show prominent 1986 or 1987 year classes.

10.3.3.1 Length at Age

Clausen and Heifetz (1999) presented revised estimates of the von Bertalanffy growth parameters for combined sexes of dusky rockfish. These were based on age samples from 1,245 fish in the 1984, 1987, 1990, and 1993 triennial surveys. The revised parameters are: L_{inf} = 45.9 cm; K = 0.24; and t_o = 1.18. A manuscript has also been prepared that presents these results in more detail (Malecha and Heifetz 2000).

10.3.3.2 Weight at Length

The best length-weight information for light dusky rockfish comes from the 1996 triennial survey, in which motion-compensated electronic scales were used to weigh a relatively large sample of individual fish for this species. For combined sexes, using the formula $W = aL^b$, where W is weight in grams and L is fork length in mm, $a = 3.28 \times 10^{-5}$ and b = 2.90 (Martin 1997).

10.4 ANALYTIC APPROACH

Due to the lack of biological information for dusky rockfish, past assessments have used a biomass-based approach based on trawl survey data to calculate ABC's for pelagic shelf rockfish. We continue to present results of this approach in the present assessment, but we also provide an alternative approach for light dusky rockfish in Appendix A that is based on age-structured modeling,

10.4.1 Assessment Parameters: Natural Mortality, Maximum Age, Age of Recruitment, and Age and Size at Maturity

Information on mortality rates and maximum age for the three species of pelagic shelf rockfish is shown in Table 10-3. These data are based on the currently accepted "break-and-burn" method of aging otoliths. The method used to determine the natural mortality rate for dusky rockfish was described in Clausen and Heifetz (1991). The dusky rockfish natural mortality rate of 0.09 is an indication that dusky rockfish is a faster growing and shorter lived species than most other rockfish. For example, mortality rates for Pacific ocean perch, northern rockfish, and other species in the shortraker/rougheye and "other slope rockfish" management groups are all <0.09, with the exception of redstripe rockfish (see the specific chapters for these management categories in this document for information about their mortality rates). The maximum age of 59 years for dusky rockfish in Table 10-3 represents the age of just a single specimen and is 8 years older than the next oldest fish that has been aged. Therefore, it may be an outlier whose validity should be viewed with some caution.

There is no published information on age or size of recruitment for any of the pelagic shelf species in Alaska. In SAFE reports before 1999, we used a very rough estimate of 7 years as the age of recruitment for dusky rockfish. However, in Clausen and Heifetz 1999 we revised this estimate to 10 years. This was based on a visual examination of the length frequency distributions for the commercial fishery, which indicated that length of 50% recruitment probably corresponds to about 40 cm. This length translates to an age of approximately 10 years, which we believe is a more reasonable estimate of age at 50% recruitment than the 7 years that we had used previously. A more precise estimate of the age at 50% recruitment will be computed in the future based on the age-structured model for light dusky rockfish.

Size at 50% maturity for a relatively small sample (n=64) of female light dusky rockfish in the Kodiak area has been estimated to be 42.8 cm fork length (Clausen and Heifetz 1997). Age data for these fish were analyzed using a logistic function, which provided an estimated age at 50% maturity of 11.3 years[6].

10.4.2 Current Exploitable Biomass

[6]C. Lunsford, National Marine Fisheries Service, Alaska Fisheries Science Center, Auke Bay Laboratory, 11305 Glacier Hwy., Juneau, AK 99801. Pers. commun. August 1999.

In the last nine SAFE reports (Clausen and Heifetz 1994, 1995, 1996, 1997, 1998, 1999, 2000, and 2001; Clausen et al. 2002), current exploitable biomass for pelagic shelf rockfish was computed by averaging the Gulfwide assemblage biomass in the most recent three trawl surveys (i.e., averaging the 1987, 1990, and 1993 surveys for the 1994 and 1995 reports, averaging the 1990, 1993, and 1996 surveys for the 1996, 1997, and 1998 reports, etc.). This averaging technique was used because of the uncertainty of the biomass estimates (discussed previously in section 10.3.2.1, "Survey Biomass Estimates") and the resultant desire to avoid placing too much emphasis on the results of an individual survey.

Therefore, the Gulfwide assemblage biomass estimates for three most recent surveys in 1999, 2001, and 2003 are 64,694 mt, 45,670 mt, and 71,899 mt respectively (Table 10-2). Averaging these values yields a current exploitable biomass of 60,754 mt for pelagic shelf rockfish. This estimate can be broken down into 53,719 mt for light dusky rockfish, 975 mt for dark dusky rockfish (54,694 mt for light and dark dusky combined), 187 mt for widow rockfish, and 5,874 mt for yellowtail rockfish (6,061 mt for widow and yellowtail combined).

An alternative estimate of current exploitable biomass for light dusky rockfish based on an age-structured model is presented in Appendix A.

10.4.3 Reference Fishing Mortality Rates and Yields for Dusky Rockfish

A spawning biomass-per-recruit analysis was applied to dusky rockfish to determine several reference values of fishing mortality (F) and corresponding yields. The computed values of F include $F_{30\%}$, $F_{35\%}$, and $F_{40\%}$. Required parameters for this analysis include an estimate of natural mortality (M), von Bertalanffy growth parameters K, t_o, and W_{inf}, and ages of maturity and recruitment. The estimates of M, K, and t_o used were those listed in section 10.3.3.1, "Length at Age" and 7.4.1, "Assessment Parameters". W_{inf} was calculated using a length-weight regression to convert L_{inf} in the "Assessment Parameters" section to a weight value. Age at 50% maturity for females was estimated at 11.3 years as listed in "Assessment Parameters" section. Recruitment was assumed to be "knife-edge", and age of recruitment was estimated at 10 years as discussed in the "Assessment Parameters" section. Yields were calculated using the exploitable biomass of 54,694 mt for dusky rockfish (light and dark forms combined) from section 10.4.2, "Current Exploitable Biomass". The computed reference values of F and another reference value, F=M, are listed in the following table, along with their corresponding yields.

	$F_{30\%}$	$F_{35\%}$	$F_{40\%}$	$F_{50\%}$	F=M
Reference value	0.169	0.136	0.110	0.075	0.090
Yield (mt)	9,243	7,438	6,016	4,102	4,922

10.5 ACCEPTABLE BIOLOGICAL CATCH

In previous stock assessments, acceptable biological catch (ABC) of pelagic shelf rockfish was estimated using the most conservative of the reference values listed above, F=M (Clausen and Heifetz 1991, 1992, 1993, 1994, and 1995). In this strategy, which was originally based on the NPFMC's old (pre-1996) definitions for overfishing and ABC, the annual exploitation rate for the assemblage was set equal to the rate of natural mortality for dusky rockfish, 0.09. New definitions for overfishing and ABC were established in 1996, and these were revised in 1999. As described below in section 7.6, "Overfishing Definition", dusky rockfish falls into tier 4 of the current definitions, in which the fishing rate that determines ABC is required to be less than or equal to $F_{40\%}$. This new definition theoretically allows a

somewhat higher ABC than the old (pre-1996) definition, as shown by the yields in the preceding section (compare the yield for $F_{40\%}$, 6,016 mt, with that for F=M, 4,922 mt). However, because of the uncertainty of the biomass estimates for dusky rockfish that was previously discussed in section 10.3.2.1, and the resultant lack of knowledge about the real trend in stock abundance for these fish, we have opted to stay with the more conservative F=M approach in the last seven assessments (Clausen and Heifetz 1996, 1997, 1998, 1999, 2000, and 2001; Clausen et al. 2002). If we again use F=M for computing the 2004 ABC, the current estimate of exploitable biomass for dusky rockfish (54,694 mt for both light and dark forms; see previous section 10.4.2) can be multiplied by an M of 0.09 to yield an ABC of 4,922 mt in 2004 for this species in the Gulf of Alaska. This ABC can be divided into 4,835 mt for light dusky rockfish and 88 mt for dark dusky rockfish, based on the estimates of exploitable biomass for each color form.

Before the Nov. 2001 SAFE report, widow and yellowtail rockfish were always lumped with dusky rockfish in the ABC computations. Exploitable biomass of widow and yellowtail rockfish was multiplied by 0.09 to determine ABC, identical to the procedure used for dusky rockfish. In effect, this meant that all three species were treated as "tier 4" species. According to the 1999 overfishing definitions, however, widow and yellowtail rockfish should be assigned to tier 5, because $F_{35\%}$ and $F_{40\%}$ are unknown for these species in Alaska. In tier 5, F_{ABC} is defined to be <=0.75 x M . To correct this error of treating widow and yellowtail rockfish as tier 4 species, we now recommend that ABC for these two fish be computed separately from dusky rockfish, and that the tier 5 formula be applied to widow and yellowtail rockfish. If we assume an M of 0.09 for the two species (the same M as used for dusky rockfish), F_{ABC} is then 0.75 x M, which equals 0.0675. Multiplying this value of F by the current exploitable biomass for widow and yellowtail rockfish (6,061 mt; see previous section 7.4.2) yields an ABC of 409 mt for 2004.

Therefore, the overall ABC in 2004 for the pelagic shelf rockfish assemblage in the Gulf of Alaska based on this approach is 4,922 mt + 409 mt = 5,332 mt. This is slightly less than our ABC recommendation for 2002 and 2003 of 5,485 mt.

An alternative approach for calculating ABC of light dusky rockfish based on an age-structured model is presented in Appendix A.

In all previous years, annual allocation of the Gulfwide ABC for pelagic shelf rockfish amongst the three regulatory areas in the Gulf has been based on the geographic distribution of pelagic shelf rockfish biomass in the trawl surveys. Since the 1996 SAFE report, this distribution has been computed as a weighted average of the percent biomass distribution for each area in the three most recent trawl surveys. In the computations, each successive survey is given a progressively heavier weighting using factors of 4, 6, and 9, respectively. This 4:6:9 weighting scheme was originally recommended by the Gulf of Alaska Groundfish Plan Team, and had already been used for Pacific ocean perch in the 1996 fishery. The Plan Team believed that for consistency among the rockfish assessments, the same weighting should be applied to pelagic shelf rockfish. The Plan Team's scheme was adopted for the 1997 fishery, and we have continued to follow it. Therefore, based on a 4:6:9 weighting of the 1999, 2001, and 2003 trawl surveys, the percent distribution of pelagic shelf rockfish biomass in the Gulf of Alaska is: Western area, 8.29%; Central area, 67.35%, and Eastern area, 24.37%. Applying these percentages to the overall ABC of 5,332 mt yields the following apportionments for the Gulf in 2004: Western area, 442 mt; Central area, 3,591 mt; and Eastern area, 1,299 mt.

Because the Eastern area is now divided into two management areas for pelagic shelf rockfish, i.e., the West Yakutat area (area between 147 degrees W. longitude and 140 degrees W. longitude) and the East Yakutat/Southeast Outside area (area east of 140 degrees W. longitude), the ABC for this management

group in the Eastern area must be further apportioned between these two smaller areas. The weighted average method described above results in a point estimate of 0.1899 for the proportion of biomass in the Eastern area that occurs in West Yakutat. (In this case the average was based on the 1996, 1999, and 2003 surveys because the 2001 survey did not sample the eastern Gulf of Alaska). This translates into an ABC of 247 mt for West Yakutat and 1,052 mt for East Yakutat/Southeast Outside in 2004. However, there is considerable uncertainty in the point estimate. In an effort to balance this uncertainty with associated costs to the fishing industry, the Gulf of Alaska Plan Team has recommended that apportionment to the two smaller areas in the eastern Gulf be based on the upper 95% confidence limit of the weighted average of the estimates of the eastern Gulf biomass proportion that is in the West Yakutat area. The upper 95% confidence interval of this proportion is .5595, so that the ABC for West Yakutat would be 727 mt, and the ABC for East Yakutat/Southeast Outside would be 572 mt.

One possible problem has arisen concerning the above apportionment scheme to determine the ABC in the West Yakutat and East Yakutat/Southeast Outside areas. The two most recent trawl surveys of the eastern Gulf of Alaska in 1999 and 2003 have found very low biomass estimates of pelagic shelf rockfish in the West Yakutat area. In these surveys, the biomass in West Yakutat only comprised 2.6% and 11.1%, respectively, of the total assemblage biomass in the eastern Gulf. In contrast, the 1990, 1993, and 1996 surveys showed the percentages in West Yakutat were 67.5, 43.8, and 61.3, respectively. If the more recent estimates reflect an actual downward shift in the proportion in West Yakutat, the current weighting scheme and use of the upper 95% confidence interval to determine this area's allocation could result in substantial localized overharvest of the fish.

10.6 OVERFISHING DEFINITION

In 1990, the NPFMC adopted a policy to prevent overfishing by requiring that fishing mortality for any stock should not exceed a prescribed maximum rate. For any given stock, a specific rate of overfishing (F_{OFL}) was defined based on the amount of population dynamics information available for the stock. In June 1996, the NPFMC approved a revised series of overfishing definitions, and these definitions were further revised in January 1999. The 1999 definitions specify that for a species such as dusky rockfish, where estimates of biomass, $F_{35\%}$, and $F_{40\%}$ are the only parameters known (i.e., tier 4 in the definitions), F_{OFL} is defined to be the $F_{35\%}$ level. The definitions also state that the fishing rate that determines ABC (F_{ABC}) should be less than or equal to $F_{40\%}$. As shown previously in the "Reference Fishing Mortality Rates and Yields" section, $F_{35\%}$ is computed to be 0.136, and $F_{40\%}$ is 0.110. These rates correspond to Gulfwide yields of 7,438 mt for overfishing and 6,016 mt for ABC, respectively. Thus, the ABC recommendation of 4,922 mt in this report for dusky rockfish in the Gulf of Alaska is consistent with the NPFMC definition because it is less than the maximum allowable ABC of 6,016 mt.

As described in Section 10.5, widow and yellowtail rockfish fall into tier 5 of the overfishing definitions, in which estimates of biomass and natural rate of mortality (M) are the only parameters known. (M is not really known for these species in Alaska, but the M for dusky rockfish, 0.09, appears to be a reasonable approximation of M for the two species.) For tier 5 species, F_{OFL} is defined to equal M, and F_{ABC} is <= 0.75 x M. These rates equate to 0.09 and 0.0675, respectively, and correspond to Gulfwide yields of 545 mt and 409 mt.

The total level of overfishing for the assemblage in the Gulf of Alaska equals the overfishing level of 7,438 mt for dusky rockfish plus the overfishing level of 545 mt for widow and yellowtail rockfish, which totals 7,983 mt.

10.7 HARVEST SCENARIOS TO SATISFY REQUIREMENTS OF NPFMC's AMENDMENT 56, NEPA, AND MSFCMA

To satisfy requirements of the NPFMC's Amendment 56, the National Environmental Policy Act (NEPA), and the Magnuson-Stevens Fishery Conservation and Management Act (MSFCMA), all stock assessments have been asked to provide a set of seven harvest scenarios for future years. For species that are assessed using an age/length-structured model (tiers 1, 2, or 3 in the overfishing definitions), these scenarios can take the form of multi-year projections. For species such as pelagic shelf rockfish that are not modeled (tier 4 or higher), such projections are not possible, but yields for just the year 2004 can be computed for scenarios 1-5 as follows:

(Note: all the computed yields are based on an exploitable biomass of 60,754 mt in 2004.)

Scenario 1: F equals the maximum permissible F_{ABC} as specified in the ABC/OFL definitions. For tier 4 species such as dusky rockfish, the maximum permissible F_{ABC} is $F_{40\%}$. $F_{40\%}$ equals 0.110, and the corresponding yield is 6,016 mt. For tier 5 species such as widow and yellowtail rockfish, the maximum permissible F_{ABC} is 0.75 x M, and the corresponding yield is 409 mt. Total yield for the assemblage would be 6,016 mt + 409 mt = 6,425 mt.

Scenario 2: F equals the stock assessment author's recommended F_{ABC}. In this assessment, the recommended F_{ABC} for dusky rockfish is F=M=0.09, and the recommended F_{ABC} for widow and yellowtail rockfish is F = 0.75 x M. Corresponding yields are 4,922 mt and 409 mt, respectively, which equals a total of 5,332 mt for the entire assemblage.

Scenario 3: F equals the 5-year average F from 1998 to 2002. Using the catch data for these years in Table 10-1a and annual exploitable biomass estimates for the assemblage, the average F for 1998 to 2002 is 0.056997, and the corresponding yield is 3,562 mt.

Scenario 4: F equals 50% of the maximum permissible F_{ABC} as specified in the ABC/OFL definitions. For dusky rockfish, 50% of $F_{40\%}$ (the maximum permissible F_{ABC}) is 0.055, and the corresponding yield is 3,008 mt. For widow and yellowtail rockfish, 50% of 0.75 x M (the maximum permissible F_{ABC}) is 0.03375, and the corresponding yield is 205 mt. Total yield for the entire assemblage under this scenario is 3,008 mt + 205 mt = 3,213 mt .

Scenario 5: F equals 0. Corresponding yield is 0.

10.8 OTHER CONSIDERATIONS

10.8.1 Management Problems Involving Dark Dusky Rockfish

Although black and blue rockfish have been removed from the pelagic shelf assemblage, one management problem that remains is the taxonomic uncertainty of dusky rockfish. The inshore habitat of dark dusky rockfish is one that this variety shares with black and blue rockfish. This suggests that from a biological perspective, it may be more logical for dark dusky rockfish to be grouped with the latter two species, rather than in the pelagic shelf assemblage. Moreover, information from ADF&G indicates that in past years a sizeable portion (perhaps 25%) of the fish reported as "black rockfish" in the Kenai Peninsula jig

fishery may have actually been dark dusky rockfish.[7] Dark dusky rockfish and black rockfish often co-occur in nearshore kelp beds of the Gulf of Alaska, and they are superficially similar in appearance, especially in body color, which leads to misidentification. As already mentioned, however, no definitive taxonomic studies have been completed that would separate the light and dark varieties of dusky rockfish into distinct species. Until results of such studies are available, we recommend for the interim that both forms of dusky rockfish remain in the pelagic shelf assemblage. In the future, if dark dusky rockfish is found to be a valid species, it may be appropriate to consider its removal from the assemblage and transfer to state jurisdiction, similar to what has been done for black and blue rockfish.

10.9 ECOSYSTEM CONSIDERATIONS

In general, a determination of ecosystem considerations for pelagic shelf rockfish is hampered by the lack of biological and habitat information for dusky rockfish. A summary of the ecosystem considerations presented in this section is listed in Table 10-4.

10.9.1 Ecosystem Effects on the Stock

Prey availability/abundance trends: similar to many other rockfish species, stock condition of dusky rockfish appears to be greatly influenced by periodic abundant year classes. Availability of suitable zooplankton prey items in sufficient quantity for larval or post-larval dusky rockfish may be an important determining factor of year class strength. Unfortunately, there is no information on the food habits of larval or post-larval rockfish to help determine possible relationships between prey availability and year class strength; moreover, field-collected larval dusky rockfish at present cannot even be visually identified to species. Adult dusky rockfish consume mostly euphausiids (Yang 1993). Euphausiids are also a major item in the diet of walleye pollock, Pacific ocean perch, and northern rockfish. Changes in the abundance of these three species could lead to a corollary change in the availability of euphausiids, which would then have an impact on dusky rockfish.

Predator population trends: there is no documentation of predation on dusky rockfish. Larger fish such as Pacific halibut that are known to prey on other rockfish may also prey on adult dusky rockfish, but such predation probably does not have a substantial impact on stock condition. Predator effects would likely be more important on larval, post-larval, and small juvenile dusky rockfish, but information on these life stages and their predators is nil.

Changes in physical environment: strong year classes corresponding to the period 1976-77 have been reported for many species of groundfish in the Gulf of Alaska, including walleye pollock, Pacific ocean perch, northern rockfish, sablefish, and Pacific cod. As discussed in Section 10.3.2.3, age data for dusky rockfish indicates that the 1976 and/or 1977 year classes were also usually strong for this species. Therefore, it appears that environmental conditions may have changed during this period in such a way that survival of young-of-the-year fish increased for many groundfish species, including dusky rockfish. The environmental mechanism for this increased survival of dusky rockfish, however, remains unknown. Pacific ocean perch and dusky rockfish both appeared to have strong 1986 year classes, and this may be another year when environmental conditions were especially favorable for rockfish species.

10.9.2 Fishery Effects on the Ecosystem

[7] W. Bechtol, Alaska Department of Fish and Game, 3298 Douglas St., Homer, AK 99603. Pers. commun. August 1995.

Fishery-specific contribution to bycatch of HAPC biota: there is limited habitat information on adult dusky rockfish, especially regarding the habitat of the major fishing grounds for this species in the Gulf of Alaska. Nearly all the catch of dusky rockfish, however, is taken by bottom trawls, so the fishery potentially could affect HAPC biota such as corals or sponges if it occurred in localities inhabited by those biota. Corals and sponges are usually found on hard, rocky substrates, and there is some evidence that dusky rockfish may be found in such habitats. On submersible dives on the outer continental shelf of the eastern Gulf of Alaska, light dusky rockfish were observed in association with rocky habitats and in areas with extensive sponge beds, where the fish were observed resting in large vase-type sponges.[8] Also, dusky rockfish often co-occur and are caught with northern rockfish in the commercial fishery and in trawl surveys (Reuter 1999), and there is information to suggest that northern rockfish are associated with a rocky or rough bottom habitat[9]. Based on this indirect evidence, it can be surmised that dusky rockfish are likely also associated with a rocky substrate. An analysis of bycatch of HAPC biota in commercial fisheries in the Gulf of Alaska in 1997-99 indicated that the dusky rockfish trawl fishery ranked fourth (after the deepwater flatfish, walleye pollock, and Pacific ocean perch bottom trawl fisheries) among all fisheries in the amount of corals taken as bycatch and sixth in the amount of sponges taken (National Marine Fisheries Service 2001). Little is known, however, about the extent of these HAPC biota and whether the bycatch is detrimental.

Fishery-specific concentration of target catch in space and time relative to predator needs in space and time (if known) and relative to spawning components: the dusky rockfish trawl fishery in the Gulf of Alaska starts in July and usually lasts only a few weeks. As mentioned previously in section 10.2.2, the fishery is concentrated at a number of offshore banks on the outer continental shelf. There is no published information on time of year of insemination or parturition (larval release), but insemination is likely in the fall or winter, and anecdotal observations indicate parturition is mostly in the spring. Hence, reproductive activities are probably not directly affected by the commercial fishery.

Fishery-specific effects on amount of large size target fish: a comparison between Figure 10-1 (length frequency in the commercial fishery) and Figure 10-4 (size composition in the trawl surveys) suggests that although the fishery does not catch many small fish <40 cm length, neither does it particularly target on very large fish.

Fishery contribution to discards and offal production: fishery discard rates of pelagic shelf rockfish have been quite low in recent years, as they have averaged only about 6% in the period 1997-2002. The discard amount of species other than pelagic shelf rockfish in the dusky rockfish fishery is unknown.

Fishery-specific effects on age-at-maturity and fecundity of the target fishery: unknown, but based on the size of 50% maturity of female dusky rockfish reported in this document (42.8 cm), the fishery length frequency distributions in Figure 10-1 suggest that in some years the fishery may be catching a sizeable number of immature fish.

Fishery-specific effects on EFH non-living substrate: unknown, but the heavy-duty "rockhopper" trawl gear commonly used in the fishery can move around rocks and boulders on the bottom.

10.9.3 Data Gaps and Research Priorities

There is no information on larval, post-larval, or early stage juvenile dusky rockfish. Larval dusky rockfish cannot even be identified in plankton samples except by using genetic techniques. Habitat requirements for larval, post-larval, and early stage juvenile dusky rockfish are completely unknown. Habitat requirements for later stage juvenile and adult fish are anecdotal or conjectural. Research needs to be done on the bottom habitat of the major fishing grounds, on what HAPC biota are found on these grounds, and on what impact bottom trawling has on these biota.

10.10 SUMMARY

A summary table of the natural mortality rate (M), biomass, exploitation rates, OFL, and ABC for pelagic shelf rockfish is presented below:

M	current exploitable biomass (mt)	F_{OFL}	maximum allowable F_{ABC}	recom-mended F_{ABC}	OFL (mt)	2004 ABC (mt)
			Dusky rockfish (light and dark forms combined)			
0.090	54,694	0.136	0.110	0.090	7,438	4,922
			Widow and yellowtail rockfish			
0.090	6,061	0.090	0.068	0.068	545	409
			Entire pelagic shelf rockfish assemblage			
0.090	60,754	-	-	-	7,983	5,332

2003	U.S.	164	2,194	617	607	10	2,975	5,490	5,490

[a]Catches for 1988-97 include black rockfish and blue rockfish, which were members of the assemblage during those years.
[b]Catches for West Yakutat and Southeast Outside areas are not available for years before 1996. Eastern area is comprised of the West Yakutat and Southeast Outside areas combined.
[c]West Yakutat area is comprised of statistical areas 640 and 649.
[d]Southeast Outside area is comprised of statistical areas 650 and 659.

Notes: There were no foreign or joint venture catches after 1988. Catches in 1988 are landed catches only. Catches in 1989-91 also include fish reported in weekly production reports as discarded by fishermen or processors. Catches in 1992-2002 also include discarded fish, as determined through a "blend" of weekly production reports and information from the domestic observer program.

Definition of terms: JV = joint venture production; U.S. = domestic annual production; Tr = trace catches.

Total, all species	4,274	46,778	7,214	11,590	2,044	71,899

[a]Note: The Yakutat and Southeastern areas were not sampled in the 2001 survey. Estimates of biomass for these two areas in 2001 were obtained by averaging the corresponding area biomasses in the 1993, 1996, and 1999 surveys.

Table 10-3.--Instantaneous rate of mortality and maximum age for pelagic shelf rockfish, based on the break-and-burn method of aging otoliths. Area indicates location of study: Gulf of Alaska (GOA) or British Columbia (BC).

Species	Mortality rate	Maximum age	Area	Reference
Dusky rockfish	0.09[a]	59	GOA	1
		51	GOA	2
Yellowtail rockfish	0.06-0.14[b]	64	BC	3, 4
Widow rockfish	0.05[b]	59	BC	4

[a]Instantaneous rate of natural mortality (M).
[b]Instantaneous rate of total mortality (Z).

Table 10-4.-- Analysis of ecosystem considerations for pelagic shelf rockfish and the dusky rockfish fishery.

Indicator	***Observation***	***Interpretation***	***Evaluation***
ECOSYSTEM EFFECTS ON STOCK			
Prey availability or abundance trends	important for larval and post-larval survival, but no information known	may help to determine year class strength	possible concern if some information available
Predator population trends	unknown		little concern for adults
Changes in habitat quality	variable	variable recruitment	possible concern
FISHERY EFFECTS ON ECOSYSTEM			
Fishery contribution to bycatch			
Prohibited species	unknown		
Forage (including herring, Atka mackerel, cod, and pollock)	unknown		
HAPC biota (seapens/whips, corals, sponges, anemones)	fishery may affect hard-bottom biota, i.e., corals, sponges	could harm the ecosystem by reducing shelter for some species	possible concern
Marine mammals and birds	probably few taken		little concern
Sensitive non-target species	unknown		
Fishery concentration in space and time	little overlap between fishery and reproductive activities	fishery does not hinder reproduction	little concern
Fishery effects on amount of large size target fish	no evidence for targeting large fish	large fish and small fish are both in population	little concern
Fishery contribution to discards and offal production	discard rates small for pelagic shelf rockfish	little unnatural input of food into the ecosystem	little concern
Fishery effects on age-at-maturity and fecundity	**fishery may be catching some immature fish**	**could reduce spawning potential and yield**	possible concern

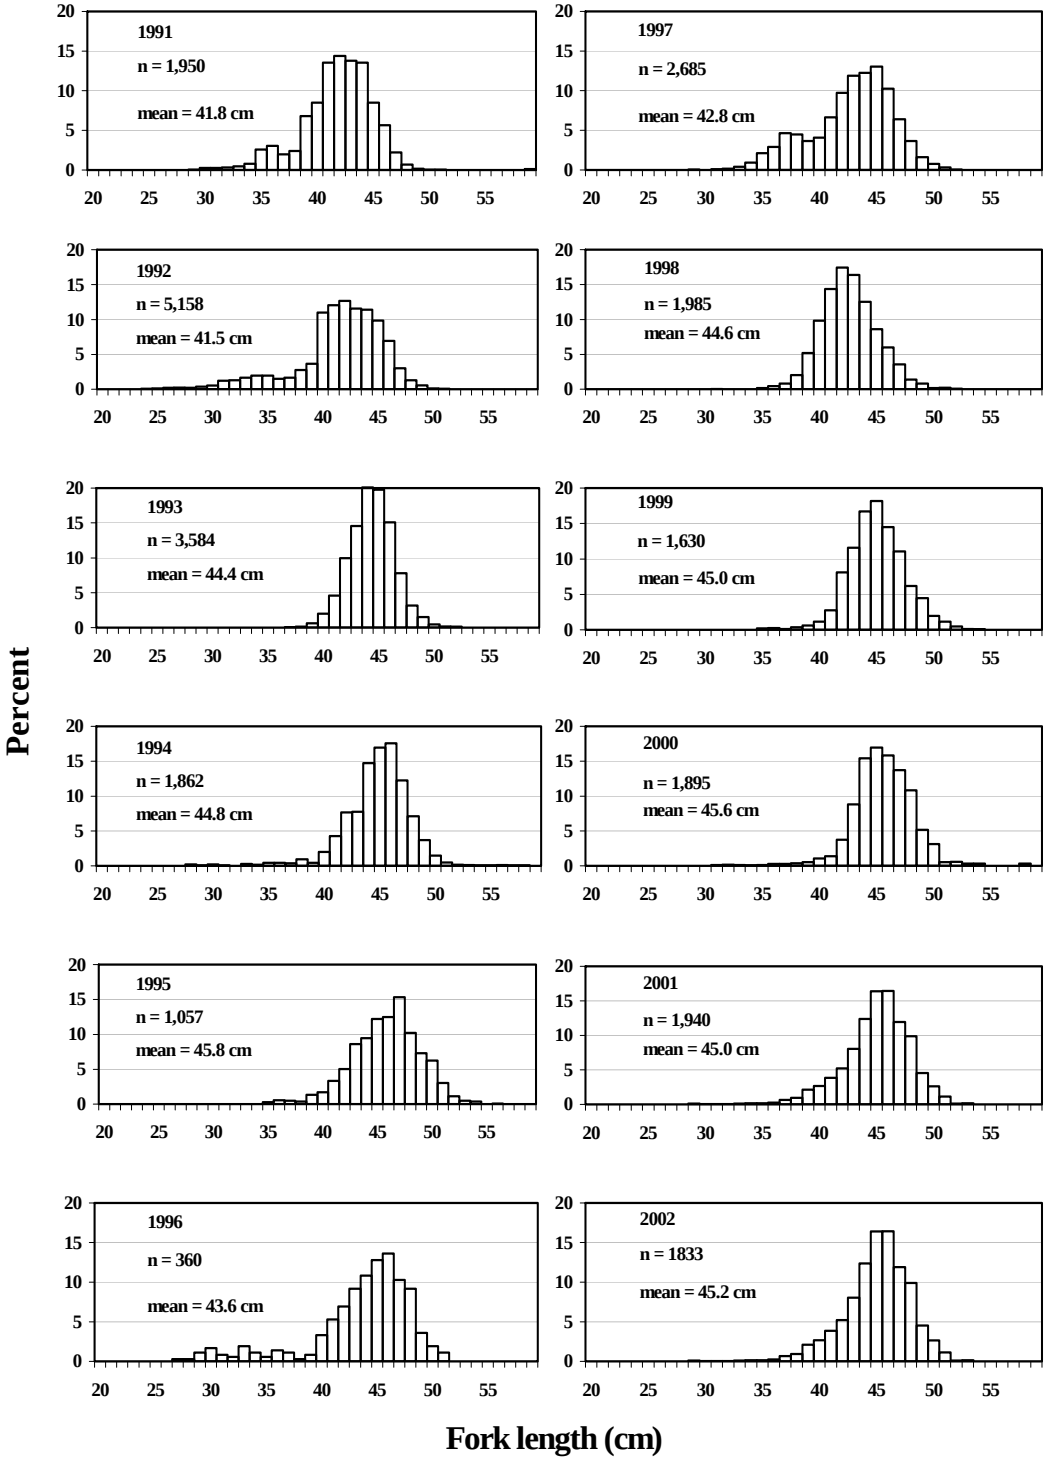

Figure 10-1.–Raw length frequency distribution of dusky rockfish measured by observers in the Gulf of Alaska commercial fishery, 1991-2002.

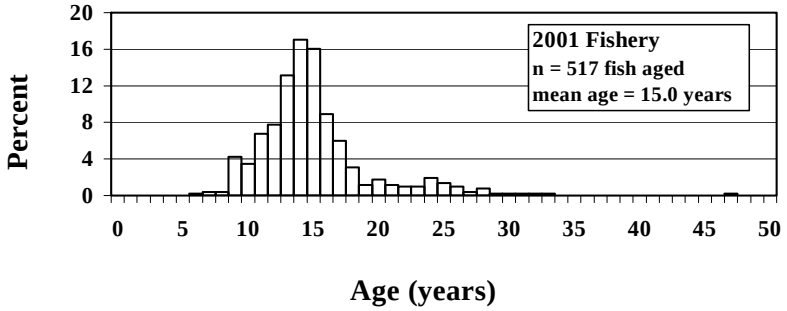

Figure 10-2.--Raw age distribution of light dusky rockfish sampled in the 2001 Gulf of Alaska commercial fishery.

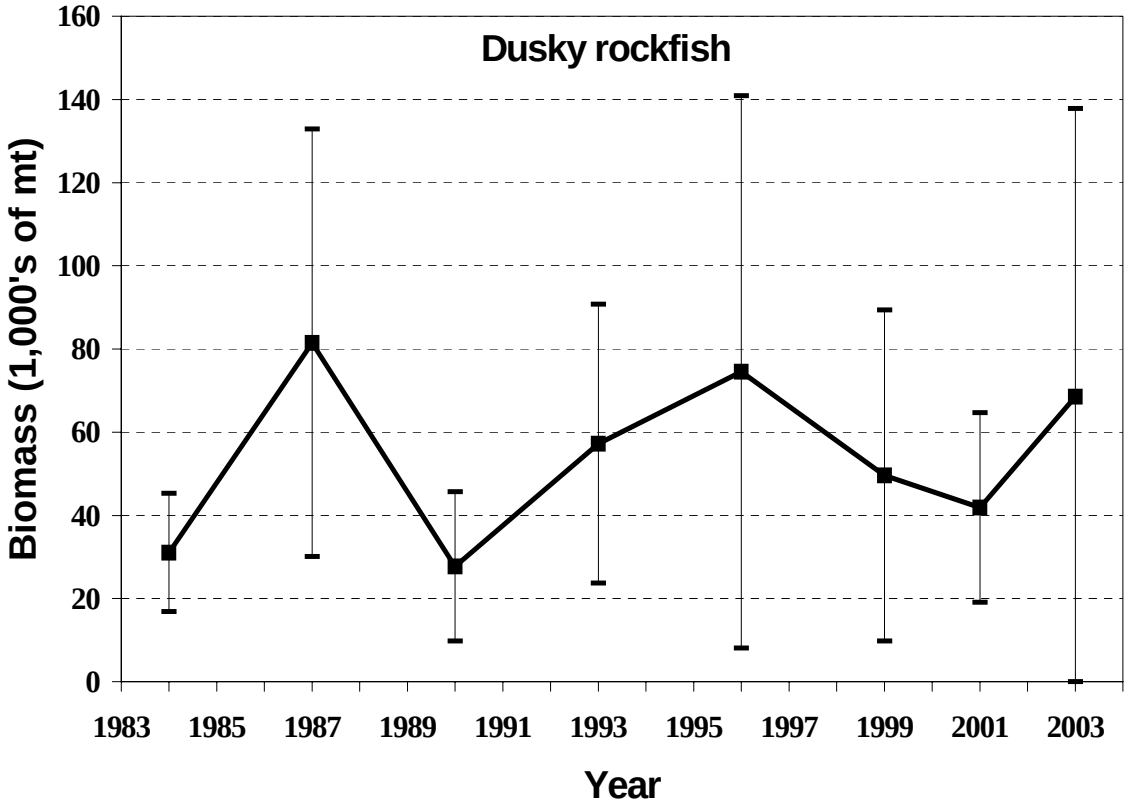

Figure 10-3.--Estimated biomass of dusky rockfish in the Gulf of Alaska based on results of bottom trawl surveys from 1984 through 2003. The vertical bars show the 95% confidence limits associated with each estimate. The eastern Gulf of Alaska was not sampled in the 2001 survey, but substitute estimates of biomass and variance for this region in 2001 were calculated and included in the above graph.

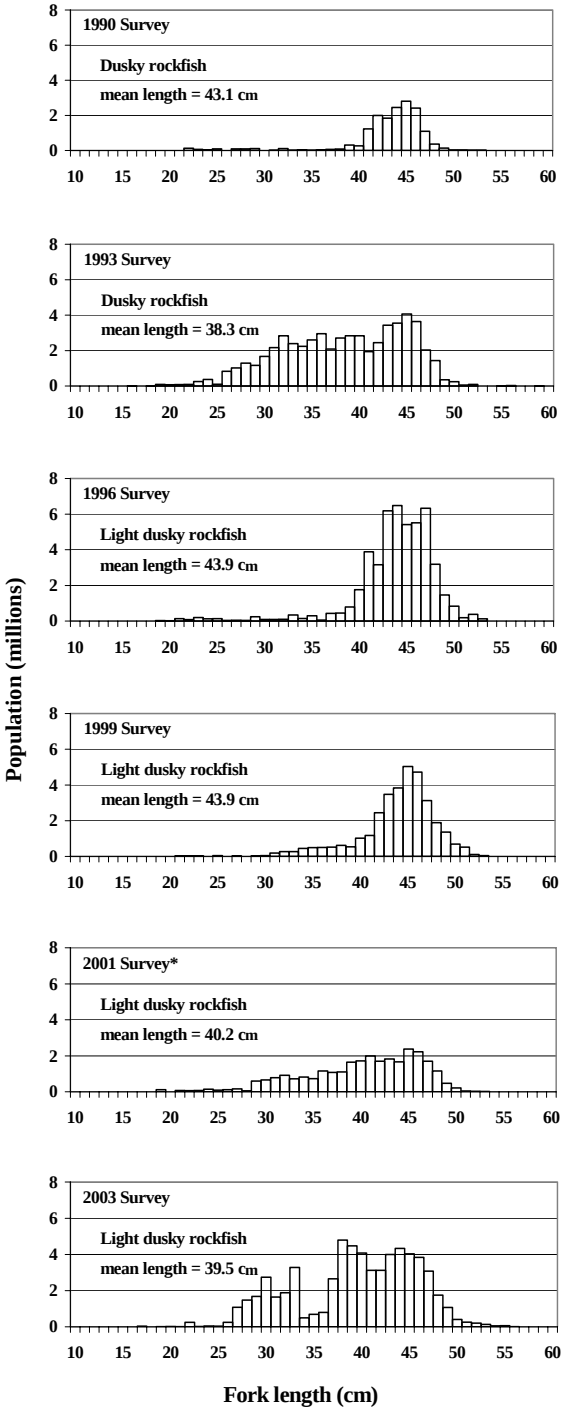

Figure 10-4.--Length frequency distribution of the estimated population of dusky rockfish in the Gulf of Alaska, based on trawls surveys in 1990 through 2003. The 1996 through 2003 distributions include data only for light dusky rockfish; in 1990 and 1993 distributions, the variety of dusky rockfish is unknown, but nearly all are believed to be the light variety. *The eastern Gulf of Alaska was not sampled in 2003.

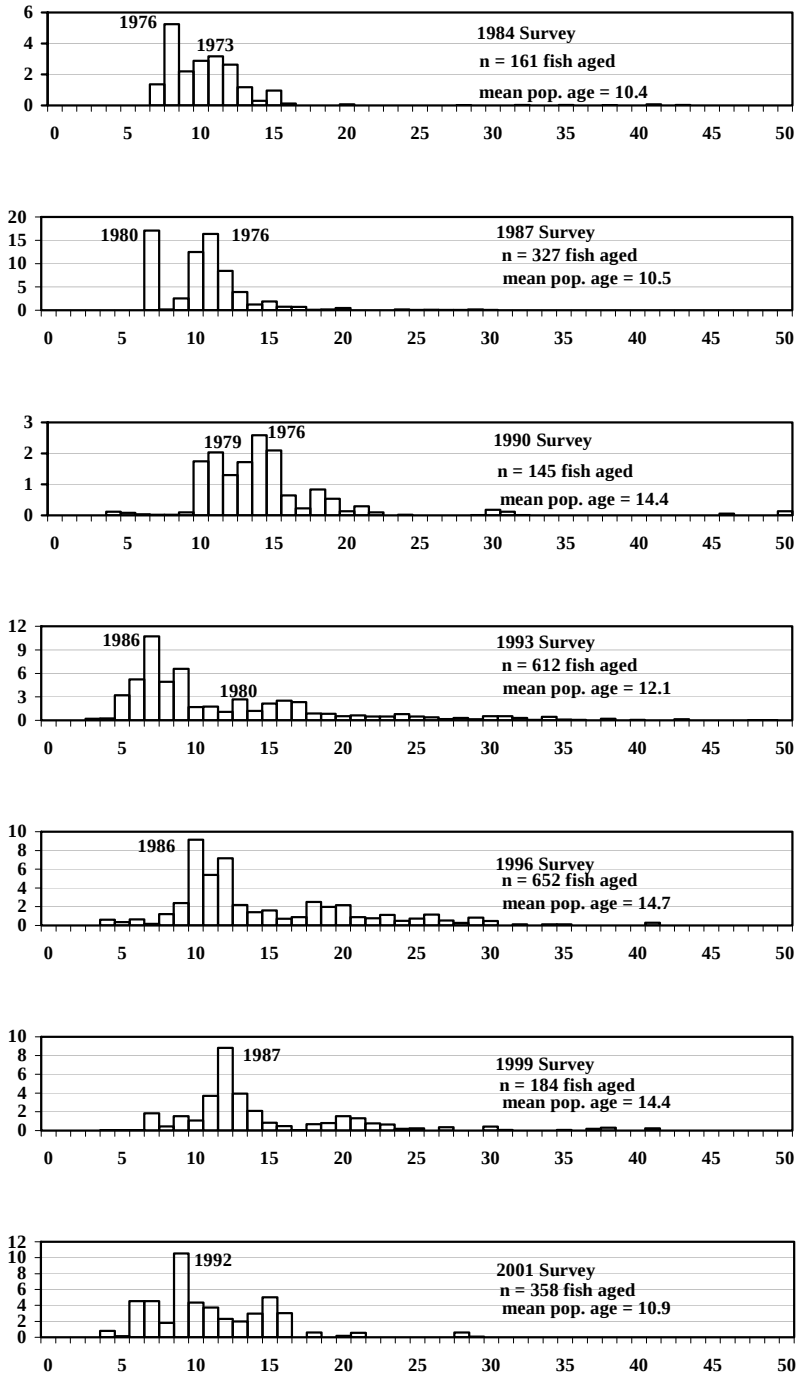

Figure 10-5.--Age composition of the estimated population of dusky rockfish in the Gulf of Alaska, based on trawl surveys from 1984 through 2001. The numbers next to prominent bar identify possibly strong year classes.
